Chapter 1
Introduction

The MCUXpresso Software Development Kit (MCUXpresso SDK) is a collection of software enablement for NXP Microcontrollers that includes peripheral drivers, multicore support, USB stack, and integrated RTOS support for FreeRTOS™ . In addition to the base enablement, the MCUXpresso SDK is augmented with demo applications, driver example projects, and API documentation to help users quickly leverage the support provided by MCUXpresso SDK. The KEx Web UI is available to provide access to all MCUXpresso SDK packages. See the *MCUXpresso Software Development Kit (SDK) Release Notes* (document MCUXSDKRN) in the Supported Devices section at MCUXpresso-SDK: Software Development Kit for MCUXpresso for details.

The MCUXpresso SDK is built with the following runtime software components:

- ARM® and DSP standard libraries, and CMSIS-compliant device header files which provide direct access to the peripheral registers.
- Peripheral drivers that provide stateless, high-performance, ease-of-use APIs. Communication drivers provide higher-level transactional APIs for a higher-performance option.
- RTOS wrapper driver built on on top of MCUXpresso SDK peripheral drivers and leverage native RTOS services to better comply to the RTOS cases.
- Real time operation systems (RTOS) for FreeRTOS OS.
- Stacks and middleware in source or object formats including:
  - A USB device, host, and OTG stack with comprehensive USB class support.
  - CMSIS-DSP, a suite of common signal processing functions.
  - The MCUXpresso SDK comes complete with software examples demonstrating the usage of the peripheral drivers, RTOS wrapper drivers, middleware, and RTOSes.

  All demo applications and driver examples are provided with projects for the following toolchains:
  - IAR Embedded Workbench
  - Keil MDK
  - MCUXpresso IDE

The peripheral drivers and RTOS driver wrappers can be used across multiple devices within the product family without modification. The configuration items for each driver are encapsulated into C language data structures. Device-specific configuration information is provided as part of the MCUXpresso SDK and need not be modified by the user. If necessary, the user is able to modify the peripheral driver and RTOS wrapper driver configuration during runtime. The driver examples demonstrate how to configure the drivers by passing the proper configuration data to the APIs. The folder structure is organized to reduce the total number of includes required to compile a project.

The rest of this document describes the API references in detail for the peripheral drivers and RTOS wrapper drivers. For the latest version of this and other MCUXpresso SDK documents, see the kex.-nxp.com/apidoc.

Chapter 3
Architectural Overview

This chapter provides the architectural overview for the MCUXpresso Software Development Kit (MCUXpresso SDK). It describes each layer within the architecture and its associated components.

Overview

The MCUXpresso SDK architecture consists of five key components listed below.

1. The ARM Cortex Microcontroller Software Interface Standard (CMSIS) CORE compliance device-specific header files, SOC Header, and CMSIS math/DSP libraries.
2. Peripheral Drivers
3. Real-time Operating Systems (RTOS)
4. Stacks and Middleware that integrate with the MCUXpresso SDK
5. Demo Applications based on the MCUXpresso SDK

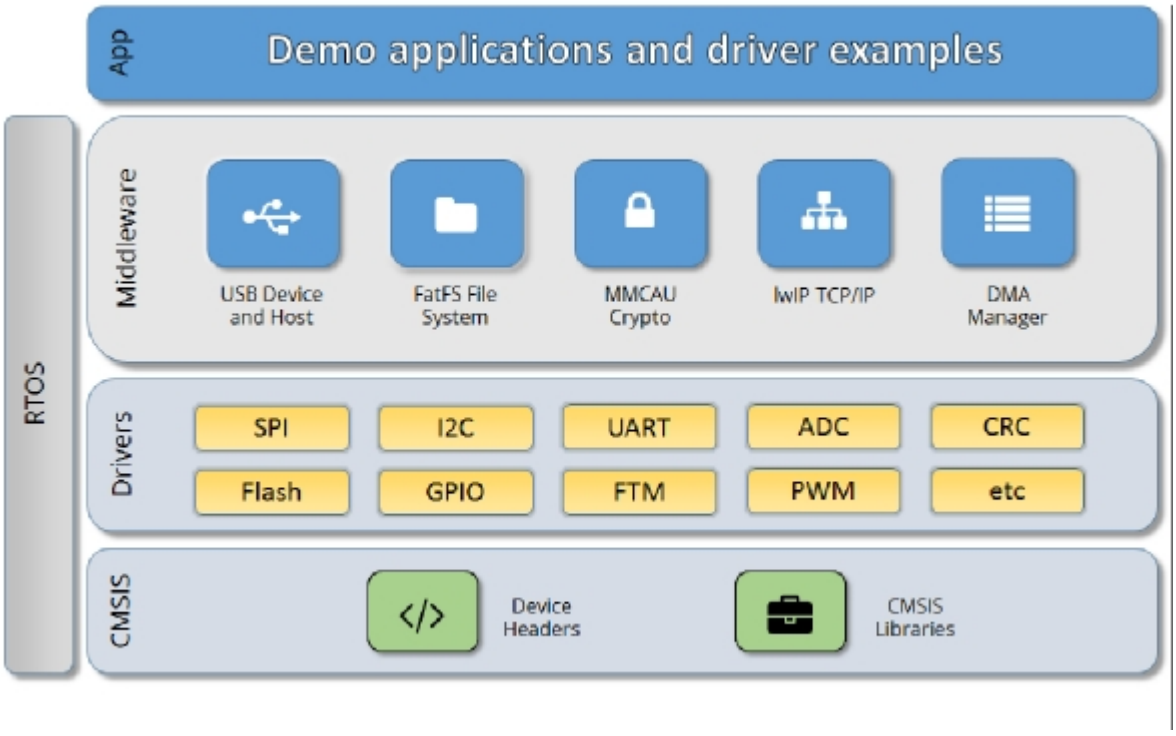

Figure 1: MCUXpresso SDK Block Diagram

MCU header files

Each supported MCU device in the MCUXpresso SDK has an overall System-on Chip (SoC) memory-

mapped header file. This header file contains the memory map and register base address for each peripheral and the IRQ vector table with associated vector numbers. The overall SoC header file provides a access to the peripheral registers through pointers and predefined bit masks. In addition to the overall SoC memory-mapped header file, the MCUXpresso SDK includes a feature header file for each device. The feature header file allows NXP to deliver a single software driver for a given peripheral. The feature file ensures that the driver is properly compiled for the target SOC.

CMSIS Support

Along with the SoC header files and peripheral extension header files, the MCUXpresso SDK also includes common CMSIS header files for the ARM Cortex-M core and the math and DSP libraries from the latest CMSIS release. The CMSIS DSP library source code is also included for reference.

MCUXpresso SDK Peripheral Drivers

The MCUXpresso SDK peripheral drivers mainly consist of low-level functional APIs for the MCU product family on-chip peripherals and also of high-level transactional APIs for some bus drivers/DMA driver/eDMA driver to quickly enable the peripherals and perform transfers.

All MCUXpresso SDK peripheral drivers only depend on the CMSIS headers, device feature files, fsl_common.h, and fsl_clock.h files so that users can easily pull selected drivers and their dependencies into projects. With the exception of the clock/power-relevant peripherals, each peripheral has its own driver. Peripheral drivers handle the peripheral clock gating/ungating inside the drivers during initialization and deinitialization respectively.

Low-level functional APIs provide common peripheral functionality, abstracting the hardware peripheral register accesses into a set of stateless basic functional operations. These APIs primarily focus on the control, configuration, and function of basic peripheral operations. The APIs hide the register access details and various MCU peripheral instantiation differences so that the application can be abstracted from the low-level hardware details. The API prototypes are intentionally similar to help ensure easy portability across supported MCUXpresso SDK devices.

Transactional APIs provide a quick method for customers to utilize higher-level functionality of the peripherals. The transactional APIs utilize interrupts and perform asynchronous operations without user intervention. Transactional APIs operate on high-level logic that requires data storage for internal operation context handling. However, the Peripheral Drivers do not allocate this memory space. Rather, the user passes in the memory to the driver for internal driver operation. Transactional APIs ensure the NVIC is enabled properly inside the drivers. The transactional APIs do not meet all customer needs, but provide a baseline for development of custom user APIs.

Note that the transactional drivers never disable an NVIC after use. This is due to the shared nature of interrupt vectors on devices. It is up to the user to ensure that NVIC interrupts are properly disabled after usage is complete.

Interrupt handling for transactional APIs

A double weak mechanism is introduced for drivers with transactional API. The double weak indicates two levels of weak vector entries. See the examples below:

```
        PUBWEAK SPI0_IRQHandler
        PUBWEAK SPI0_DriverIRQHandler
SPI0_IRQHandler
```

```
LDR     R0, =SPI0_DriverIRQHandler
BX      R0
```

The first level of the weak implementation are the functions defined in the vector table. In the devices/<-DEVICE_NAME>/<TOOLCHAIN>/startup_<DEVICE_NAME>.s/.S file, the implementation of the first layer weak function calls the second layer of weak function. The implementation of the second layer weak function (ex. SPI0_DriverIRQHandler) jumps to itself (B .). The MCUXpresso SDK drivers with transactional APIs provide the reimplementation of the second layer function inside of the peripheral driver. If the MCUXpresso SDK drivers with transactional APIs are linked into the image, the SPI0_-DriverIRQHandler is replaced with the function implemented in the MCUXpresso SDK SPI driver.

The reason for implementing the double weak functions is to provide a better user experience when using the transactional APIs. For drivers with a transactional function, call the transactional APIs and the drivers complete the interrupt-driven flow. Users are not required to redefine the vector entries out of the box. At the same time, if users are not satisfied by the second layer weak function implemented in the MCU-Xpresso SDK drivers, users can redefine the first layer weak function and implement their own interrupt handler functions to suit their implementation.

The limitation of the double weak mechanism is that it cannot be used for peripherals that share the same vector entry. For this use case, redefine the first layer weak function to enable the desired peripheral interrupt functionality. For example, if the MCU's UART0 and UART1 share the same vector entry, redefine the UART0_UART1_IRQHandler according to the use case requirements.

Feature Header Files

The peripheral drivers are designed to be reusable regardless of the peripheral functional differences from one MCU device to another. An overall Peripheral Feature Header File is provided for the MCUXpresso SDK-supported MCU device to define the features or configuration differences for each sub-family device.

5.6.14 void ADC16_SetChannelConfig (ADC_Type * *base*, uint32_t *channelGroup*, const adc16_channel_config_t * *config*)

This operation triggers the conversion when in software trigger mode. When in hardware trigger mode, this API configures the channel while the external trigger source helps to trigger the conversion.

Note that the "Channel Group" has a detailed description. To allow sequential conversions of the ADC to be triggered by internal peripherals, the ADC has more than one group of status and control registers, one for each conversion. The channel group parameter indicates which group of registers are used, for example, channel group 0 is for Group A registers and channel group 1 is for Group B registers. The channel groups are used in a "ping-pong" approach to control the ADC operation. At any point, only one of the channel groups is actively controlling ADC conversions. The channel group 0 is used for both software and hardware trigger modes. Channel group 1 and greater indicates multiple channel group registers for use only in hardware trigger mode. See the chip configuration information in the appropriate MCU reference manual for the number of SC1n registers (channel groups) specific to this device. Channel group 1 or greater are not used for software trigger operation. Therefore, writing to these channel groups does not initiate a new conversion. Updating the channel group 0 while a different channel group is actively controlling a conversion is allowed and vice versa. Writing any of the channel group registers while that specific channel group is actively controlling a conversion aborts the current conversion.

Parameters

base	ADC16 peripheral base address.
channelGroup	Channel group index.
config	Pointer to the "adc16_channel_config_t" structure for the conversion channel.

5.6.15 static uint32_t ADC16_GetChannelConversionValue (ADC_Type * *base*, uint32_t *channelGroup*) [inline], [static]

base	ADC16 peripheral base address.
channelGroup	Channel group index.

Returns

CMP: Analog Comparator Driver

6.1 Overview

The MCUXpresso SDK provides a peripheral driver for the Analog Comparator (CMP) module of MCUXpresso SDK devices.

The CMP driver is a basic comparator with advanced features. The APIs for the basic comparator enable the CMP to compare the two voltages of the two input channels and create the output of the comparator result. The APIs for advanced features can be used as the plug-in functions based on the basic comparator. They can process the comparator's output with hardware support.

This function initializes the CMP module. The operations included are as follows.

- Enabling the clock for CMP module.
- Configuring the comparator.
- Enabling the CMP module. Note that for some devices, multiple CMP instances share the same clock gate. In this case, to enable the clock for any instance enables all CMPs. See the appropriate MCU reference manual for the clock assignment of the CMP.

This function de-initializes the CMP module. The operations included are as follows.

- Disabling the CMP module.
- Disabling the clock for CMP module.

This function disables the clock for the CMP. Note that for some devices, multiple CMP instances share the same clock gate. In this case, before disabling the clock for the CMP, ensure that all the CMP instances are not used.

Parameters

base	CMP peripheral base address.

enable	Enables or disables the module.

6.6.4 void CMP_GetDefaultConfig (cmp_config_t * *config*)

Chapter 7
CMT: Carrier Modulator Transmitter Driver

7.1 Overview

The carrier modulator transmitter (CMT) module provides the means to generate the protocol timing and carrier signals for a side variety of encoding schemes. The CMT incorporates hardware to off-load the critical and/or lengthy timing requirements associated with signal generation from the CPU. The MCUXpresso SDK provides a driver for the CMT module of the MCUXpresso SDK devices.

7.2 Clock formulas

The CMT module has internal clock dividers. It was originally designed to be based on an 8 MHz bus clock that can be divided by 1, 2, 4, or 8 according to the specification. To be compatible with a higher bus frequency, the primary prescaler (PPS) was developed to receive a higher frequency and generate a clock enable signal called an intermediate frequency (IF). The IF must be approximately equal to 8 MHz and works as a clock enable to the secondary prescaler. For the PPS, the prescaler is selected according to the bus clock to generate an intermediate clock approximate to 8 MHz and is selected as (bus_clock_hz/8000000). The secondary prescaler is the "cmtDivider". The clocks for the CMT module are listed below.

1. CMT clock frequency = bus_clock_Hz / (bus_clock_Hz / 8000000) / cmtDivider
2. CMT carrier and generator frequency = CMT clock frequency / (highCount1 + lowCount1)
   (In FSK mode, the second frequency = CMT clock frequency / (highCount2 + lowCount2))
3. CMT infrared output signal frequency
   a. In Time and Baseband mode
   CMT IRO signal mark time = (markCount + 1) / (CMT clock frequency / 8)
   CMT IRO signal space time = spaceCount / (CMT clock frequency / 8)
   b. In FSK mode
   CMT IRO signal mark time = (markCount + 1) / CMT carrier and generator frequency
   CMT IRO signal space time = spaceCount / CMT carrier and generator frequency

7.3 Typical use case

This is an example code to initialize data.

```
cmt_config_t config;
cmt_modulate_config_t modulateConfig;
uint32_t busClock;

// Gets the bus clock for the CMT module.
busClock = CLOCK_GetFreq(kCLOCK_BusClk);

CMT_GetDefaultConfig(&config);

// Interrupts is enabled to change the modulate mark and space count.
config.isInterruptEnabled = true;
```

Typical use case

```
CMT_Init(CMT, &config, busClock);

// Prepares the modulate configuration for a use case.
modulateConfig.highCount1 = ...;
modulateConfig.lowCount1 = ...;
modulateConfig.markCount = ...;
modulateConfig.spaceCount = ...;

// Sets the time mode.
CMT_SetMode(CMT, kCMT_TimeMode, &modulateConfig);
```

This is an example IRQ handler to change the mark and space count to complete data modulation.

```
// The data length has been transmitted.
uint32_t g_CmtDataBitLen;

void CMT_IRQHandler(void)
{
    if (CMT_GetStatusFlags(CMT))
    {
        if (g_CmtDataBitLen <= CMT_TEST_DATA_BITS)
        {
            // LSB.
            if (data & ((uint32_t)0x01 << g_CmtDataBitLen))
            {
                CMT_SetModulateMarkSpace(CMT, g_CmtModDataOneMarkCount,
      g_CmtModDataOneSpaceCount);
            }
            else

Returns

Current status of the end of cycle status flag
- non-zero: End-of-cycle has occurred.
- zero: End-of-cycle has not yet occurred since the flag last cleared.

Chapter 8
CRC: Cyclic Redundancy Check Driver

8.1 Overview

The MCUXpresso SDK provides a Peripheral driver for the Cyclic Redundancy Check (CRC) module of MCUXpresso SDK devices.

The cyclic redundancy check (CRC) module generates 16/32-bit CRC code for error detection. The CRC module also provides a programmable polynomial, seed, and other parameters required to implement a 16-bit or 32-bit CRC standard.

8.2 CRC Driver Initialization and Configuration

CRC_Init() function enables the clock gate for the CRC module in the SIM module and fully (re-)configures the CRC module according to the configuration structure. The seed member of the configuration structure is the initial checksum for which new data can be added to. When starting a new checksum computation, the seed is set to the initial checksum per the CRC protocol specification. For continued checksum operation, the seed is set to the intermediate checksum value as obtained from previous calls to CRC_Get16bitResult() or CRC_Get32bitResult() function. After calling the CRC_Init(), one or multiple CRC_WriteData() calls follow to update the checksum with data and CRC_Get16bitResult() or CRC_Get32bitResult() follow to read the result. The crcResult member of the configuration structure determines whether the CRC_Get16bitResult() or CRC_Get32bitResult() return value is a final checksum or an intermediate checksum. The CRC_Init() function can be called as many times as required allowing for runtime changes of the CRC protocol.

CRC_GetDefaultConfig() function can be used to set the module configuration structure with parameters for CRC-16/CCIT-FALSE protocol.

8.3 CRC Write Data

The CRC_WriteData() function adds data to the CRC. Internally, it tries to use 32-bit reads and writes for all aligned data in the user buffer and 8-bit reads and writes for all unaligned data in the user buffer. This function can update the CRC with user-supplied data chunks of an arbitrary size, so one can update the CRC byte by byte or with all bytes at once. Prior to calling the CRC configuration function CRC_Init() fully specifies the CRC module configuration for the CRC_WriteData() call.

8.4 CRC Get Checksum

The CRC_Get16bitResult() or CRC_Get32bitResult() function reads the CRC module data register. Depending on the prior CRC module usage, the return value is either an intermediate checksum or the final checksum. For example, for 16-bit CRCs the following call sequences can be used.

CRC_Init() / CRC_WriteData() / CRC_Get16bitResult() to get the final checksum.

CRC_Init() / CRC_WriteData() / ... / CRC_WriteData() / CRC_Get16bitResult() to get the final checksum.

CRC_Init() / CRC_WriteData() / CRC_Get16bitResult() to get an intermediate checksum.

CRC_Init() / CRC_WriteData() / ... / CRC_WriteData() / CRC_Get16bitResult() to get an intermediate checksum.

8.5 Comments about API usage in RTOS

If multiple RTOS tasks share the CRC module to compute checksums with different data and/or protocols, the following needs to be implemented by the user.

The triplets

CRC_Init() / CRC_WriteData() / CRC_Get16bitResult() or CRC_Get32bitResult()

The triplets are protected by the RTOS mutex to protect the CRC module against concurrent accesses from different tasks. This is an example.

```
CRC_Module_RTOS_Mutex_Lock;
CRC_Init();
CRC_WriteData();
CRC_Get16bitResult();
CRC_Module_RTOS_Mutex_Unlock;
```

8.6 Comments about API usage in interrupt handler

All APIs can be used from an interrupt handler although an interrupt latency of equal and lower priority interrupts increases. The user must protect against concurrent accesses from different interrupt handlers and/or tasks.

8.7 CRC Driver Examples

8.7.1 Simple examples

This is an example with the default CRC-16/CCIT-FALSE protocol.

```
crc_config_t config;
CRC_Type *base;
uint8_t data[] = {0x00, 0x01, 0x02, 0x03, 0x04};
uint16_t checksum;

base = CRC0;
CRC_GetDefaultConfig(base, &config); /* default gives CRC-16/CCIT-FALSE */
CRC_Init(base, &config);
CRC_WriteData(base, data, sizeof(data));
checksum = CRC_Get16bitResult(base);
```

This is an example with the CRC-32 protocol configuration.

```
crc_config_t config;
uint32_t checksum;

config.polynomial = 0x04C11DB7u;
config.seed = 0xFFFFFFFFu;
config.crcBits = kCrcBits32;
config.reflectIn = true;
```

```
config.reflectOut = true;
config.complementChecksum = true;
config.crcResult = kCrcFinalChecksum;

CRC_Init(base, &config);
/* example: update by 1 byte at time */
while (dataSize)
{
    uint8_t c = GetCharacter();
    CRC_WriteData(base, &c, 1);
    dataSize--;
}
checksum = CRC_Get32bitResult(base);
```

8.7.2 Advanced examples

Assuming there are three tasks/threads, each using the CRC module to compute checksums of a different protocol, with context switches.

First, prepare the three CRC module initialization functions for three different protocols CRC-16 (ARC), CRC-16/CCIT-FALSE, and CRC-32. The table below lists the individual protocol specifications. See also http://reveng.sourceforge.net/crc-catalogue/.

	CRC-16/CCIT-FALSE	CRC-16	CRC-32
Width	16 bits	16 bits	32 bits
Polynomial	0x1021	0x8005	0x04C11DB7
Initial seed	0xFFFF	0x0000	0xFFFFFFFF
Complement checksum	No	No	Yes
Reflect In	No	Yes	Yes
Reflect Out	No	Yes	Yes

These are the corresponding initialization functions.

```
void InitCrc16_CCIT(CRC_Type *base, uint32_t seed, bool isLast)
{
    crc_config_t config;

    config.polynomial = 0x1021;
    config.seed = seed;
    config.reflectIn = false;
    config.reflectOut = false;
    config.complementChecksum = false;
    config.crcBits = kCrcBits16;
    config.crcResult = isLast?kCrcFinalChecksum:
      kCrcIntermediateChecksum;

    CRC_Init(base, &config);
}

void InitCrc16(CRC_Type *base, uint32_t seed, bool isLast)
{
    crc_config_t config;
```

```
    config.polynomial = 0x8005;
    config.seed = seed;
    config.reflectIn = true;
    config.reflectOut = true;
    config.complementChecksum = false;
    config.crcBits = kCrcBits16;
    config.crcResult = isLast?kCrcFinalChecksum:
      kCrcIntermediateChecksum;

    CRC_Init(base, &config);
}

void InitCrc32(CRC_Type *base, uint32_t seed, bool isLast)
{
    crc_config_t config;

    config.polynomial = 0x04C11DB7U;
    config.seed = seed;
    config.reflectIn = true;
    config.reflectOut = true;
    config.complementChecksum = true;
    config.crcBits = kCrcBits32;
    config.crcResult = isLast?kCrcFinalChecksum:
      kCrcIntermediateChecksum;

    CRC_Init(base, &config);
}
```

The following context switches show a possible API usage.

```
uint16_t checksumCrc16;
uint32_t checksumCrc32;
uint16_t checksumCrc16Ccit;

checksumCrc16 = 0x0;

Chapter 9
DAC: Digital-to-Analog Converter Driver

9.1 Overview

The MCUXpresso SDK provides a peripheral driver for the Digital-to-Analog Converter (DAC) module of MCUXpresso SDK devices.

The DAC driver includes a basic DAC module (converter) and a DAC buffer.

The basic DAC module supports operations unique to the DAC converter in each DAC instance. The APIs in this part are used in the initialization phase, which enables the DAC module in the application. The APIs enable/disable the clock, enable/disable the module, and configure the converter. Call the initial APIs to prepare the DAC module for the application. The DAC buffer operates the DAC hardware buffer. The DAC module supports a hardware buffer to keep a group of DAC values to be converted. This feature supports updating the DAC output value automatically by triggering the buffer read pointer to move in the buffer. Use the APIs to configure the hardware buffer's trigger mode, watermark, work mode, and use size. Additionally, the APIs operate the DMA, interrupts, flags, the pointer (the index of the buffer), item values, and so on.

Note that the most functional features are designed for the DAC hardware buffer.

9.2 Typical use case

9.2.1 Working as a basic DAC without the hardware buffer feature

```
// ...

// Configures the DAC.
DAC_GetDefaultConfig(&dacConfigStruct);
DAC_Init(DEMO_DAC_INSTANCE, &dacConfigStruct);
DAC_Enable(DEMO_DAC_INSTANCE, true);
DAC_SetBufferReadPointer(DEMO_DAC_INSTANCE, 0U);

// ...

DAC_SetBufferValue(DEMO_DAC_INSTANCE, 0U, dacValue);
```

9.2.2 Working with the hardware buffer

```
    // ...

    EnableIRQ(DEMO_DAC_IRQ_ID);

    // ...

    // Configures the DAC.
    DAC_GetDefaultConfig(&dacConfigStruct);
    DAC_Init(DEMO_DAC_INSTANCE, &dacConfigStruct);
    DAC_Enable(DEMO_DAC_INSTANCE, true);
```

Parameters

base	DSPI peripheral address.
whichCtar	The desired Clock and Transfer Attributes Register (CTAR) of the type dspi_ctar_selection_t
baudRate_Bps	The desired baud rate in bits per second

These delay names are available in the type dspi_delay_type_t.

The user passes the delay to the configuration along with the prescaler and scaler value. This allows the user to directly set the prescaler/scaler values if pre-calculated or to manually increment either value.

Parameters

base	DSPI peripheral address.
whichCtar	The desired Clock and Transfer Attributes Register (CTAR) of type dspi_ctar_selection_t.

prescaler	The prescaler delay value (can be an integer 0, 1, 2, or 3).

These delay names are available in the type dspi_delay_type_t.

The user passes which delay to configure along with the desired delay value in nanoseconds. The function calculates the values needed for the prescaler and scaler. Note that returning the calculated delay as an exact delay match may not be possible. In this case, the closest match is calculated without going below the desired delay value input. It is possible to input a very large delay value that exceeds the capability of the part, in which case the maximum supported delay is returned. The higher-level peripheral driver alerts the user of an out of range delay input.

Parameters

base	DSPI peripheral address.
whichCtar	The desired Clock and Transfer Attributes Register (CTAR) of type dspi_ctar_selection_t.
whichDelay	The desired delay to configure, must be of type dspi_delay_type_t

desired Clock and Transfer Attributes register to use for the associated SPI frame, the desired PCS signal to use for the data transfer, whether the current transfer is the last in the queue, and whether to clear the transfer count (normally needed when sending the first frame of a data packet). This is an example.

```

```
*  dspi_command_data_config_t  command;

*
```

Parameters

11.2.7.28 void DSPI_MasterWriteDataBlocking (SPI_Type * *base,* dspi_command_data_config_t * *command,* uint16_t *data*)

In master mode, the 16-bit data is appended to the 16-bit command info. The command portion provides characteristics of the data, such as the optional continuous chip select operation between transfers, the desired Clock and Transfer Attributes register to use for the associated SPI frame, the desired PCS signal to use for the data transfer, whether the current transfer is the last in the queue, and whether to clear the transfer count (normally needed when sending the first frame of a data packet). This is an example.

```
*  dspi_command_config_t commandConfig;
*  commandConfig.isPcsContinuous = true;
*  commandConfig.whichCtar = kDSPICtar0;
```

```
*  commandConfig.whichPcs = kDSPIPcs1;
*  commandConfig.clearTransferCount = false;
*  commandConfig.isEndOfQueue = false;
*  DSPI_MasterWriteDataBlocking(base, &commandConfig, dataWord);
*
```

Note that this function does not return until after the transmit is complete. Also note that the DSPI must be enabled and running to transmit data (MCR[MDIS] & [HALT] = 0). Because the SPI is a synchronous protocol, the received data is available when the transmit completes.

Parameters

base	DSPI peripheral address.
command	Pointer to the command structure.
data	The data word to be sent.

11.2.7.29 static uint32_t DSPI_MasterGetFormattedCommand (dspi_command_data_config_t * *command*) [inline], [static]

This function allows the caller to pass in the data command structure and returns the command word formatted according to the DSPI PUSHR register bit field placement. The user can then "OR" the returned command word with the desired data to send and use the function DSPI_HAL_WriteCommandDataMastermode or DSPI_HAL_WriteCommandDataMastermodeBlocking to write the entire 32-bit command data word to the PUSHR. This helps improve performance in cases where the command structure is constant. For example, the user calls this function before starting a transfer to generate the command word. When they are ready to transmit the data, they OR this formatted command word with the desired data to transmit. This process increases transmit performance when compared to calling send functions, such as DSPI_HAL_WriteDataMastermode, which format the command word each time a data word is to be sent.

Parameters

command	Pointer to the command structure.

Returns

The command word formatted to the PUSHR data register bit field.

11.2.7.30 void DSPI_MasterWriteCommandDataBlocking (SPI_Type * *base*, uint32_t *data*)

In this function, the user must append the 16-bit data to the 16-bit command information and then provide the total 32-bit word as the data to send. The command portion provides characteristics of the data, such as the optional continuous chip select operation between transfers, the desired Clock and Transfer Attributes

register to use for the associated SPI frame, the desired PCS signal to use for the data transfer, whether the current transfer is the last in the queue, and whether to clear the transfer count (normally needed when sending the first frame of a data packet). The user is responsible for appending this command with the data to send. This is an example:

```
*  dataWord = <16-bit command> | <16-bit data>;
*  DSPI_MasterWriteCommandDataBlocking(base, dataWord);
*
```

Note that this function does not return until after the transmit is complete. Also note that the DSPI must be enabled and running to transmit data (MCR[MDIS] & [HALT] = 0). Because the SPI is a synchronous protocol, the received data is available when the transmit completes.

For a blocking polling transfer, see methods below. Option 1: uint32_t command_to_send = DSPI_MasterGetFormattedCommand(&command); uint32_t data0 = command_to_send | data_need_to_send_0; uint32_t data1 = command_to_send | data_need_to_send_1; uint32_t data2 = command_to_send | data_need_to_send_2;

DSPI_MasterWriteCommandDataBlocking(base,data0); DSPI_MasterWriteCommandDataBlocking(base,data1); DSPI_MasterWriteCommandDataBlocking(base,data2);

Option 2: DSPI_MasterWriteDataBlocking(base,&command,data_need_to_send_0); DSPI_MasterWriteDataBlocking(base,&command,data_need_to_send_1); DSPI_MasterWriteDataBlocking(base,&command,data_need_to_send_2);

Parameters

base	DSPI peripheral address.
data	The data word (command and data combined) to be sent.

12.3.1.0.0.25 Field Documentation

12.3.1.0.0.25.1 bool edma_config_t::enableContinuousLinkMode

Upon minor loop completion, the channel activates again if that channel has a minor loop channel link enabled and the link channel is itself.

Returns

Major loop count which has not been transferred yet for the current TCD.

Note

1. This function can only be used to get unfinished major loop count of transfer without the next TCD, or it might be inaccuracy.
   1. The unfinished/remaining transfer bytes cannot be obtained directly from registers while the channel is running. Because to calculate the remaining bytes, the initial NBYTES configured in DMA_TCDn_NBYTES_MLNO register is needed while the eDMA IP does not support getting it while a channel is active. In another word, the NBYTES value reading is always the actual (decrementing) NBYTES value the dma_engine is working with while a channel is running. Consequently, to get the remaining transfer bytes, a software-saved initial value of NBYTES (for example copied before enabling the channel) is needed. The formula to calculate it is shown below: RemainingBytes = RemainingMajorLoopCount * NBYTES(initially configured)

This function clears the channel major interrupt flag and calls the callback function if it is not NULL.

Note: For the case using TCD queue, when the major iteration count is exhausted, additional operations are performed. These include the final address adjustments and reloading of the BITER field into the CITER. Assertion of an optional interrupt request also occurs at this time, as does a possible fetch of a new TCD from memory using the scatter/gather address pointer included in the descriptor (if scatter/gather is enabled).

For instance, when the time interrupt of TCD[0] happens, the TCD[1] has already been loaded into the eDMA engine. As sga and sga_index are calculated based on the DLAST_SGA bitfield lies in the TCD_CSR register, the sga_index in this case should be 2 (DLAST_SGA of TCD[1] stores the address of TCD[2]). Thus, the "tcdUsed" updated should be (tcdUsed - 2U) which indicates the number of TCDs can be loaded in the memory pool (because TCD[0] and TCD[1] have been loaded into the eDMA engine at this point already.).

For the last two continuous ISRs in a scatter/gather process, they both load the last TCD (The last ISR does not load a new TCD) from the memory pool to the eDMA engine when major loop completes. Therefore, ensure that the header and tcdUsed updated are identical for them. tcdUsed are both 0 in this case as no TCD to be loaded.

See the "eDMA basic data flow" in the eDMA Functional description part of the Reference Manual for further details.

Parameters

handle	eDMA handle pointer.

Chapter 13
ENET: Ethernet MAC Driver

13.1 Overview

The MCUXpresso SDK provides a peripheral driver for the 10/100 Mbps Ethernet MAC (ENET) module of MCUXpresso SDK devices.

The MII interface is the interface connected with MAC and PHY. the Serial management interface - MII management interface should be set before any access to the external PHY chip register. Call ENET_SetSMI() to initialize MII management interface. Use ENET_StartSMIRead(), ENET_StartSMIWrite(), and ENET_ReadSMIData() to read/write to PHY registers. This function group sets up the MII and serial management SMI interface, gets data from the SMI interface, and starts the SMI read and write command. Use ENET_SetMII() to configure the MII before successfully getting data from the external PHY.

This group sets/gets the ENET mac address and the multicast group address filter. ENET_AddMulticastGroup() should be called to add the ENET MAC to the multicast group. The IEEE 1588 feature requires receiving the PTP message.

For ENET receive, the ENET_GetRxFrameSize() function must be called to get the received data size. Then, call the ENET_ReadFrame() function to get the received data. If the received error occurs, call the ENET_GetRxErrBeforeReadFrame() function after ENET_GetRxFrameSize() and before ENET_ReadFrame() functions to get the detailed error information.

For ENET transmit, call the ENET_SendFrame() function to send the data out. The transmit data error information is only accessible for the IEEE 1588 enhanced buffer descriptor mode. When the ENET_ENHANCEDBUFFERDESCRIPTOR_MODE is defined, the ENET_GetTxErrAfterSendFrame() can be used to get the detail transmit error information. The transmit error information can only be updated by uDMA after the data is transmitted. The ENET_GetTxErrAfterSendFrame() function is recommended to be called on the transmit interrupt handler.

This function group configures the PTP IEEE 1588 feature, starts/stops/gets/sets/adjusts the PTP IEEE 1588 timer, gets the receive/transmit frame timestamp, and PTP IEEE 1588 timer channel feature setting.

The ENET_Ptp1588Configure() function must be called when the ENET_ENHANCEDBUFFERDESCRIPTOR_MODE is defined and the IEEE 1588 feature is required. The ENET_GetRxFrameTime() and ENET_GetTxFrameTime() functions are called by the PTP stack to get the timestamp captured by the ENET driver.

13.2 Typical use case

13.2.1 ENET Initialization, receive, and transmit operations

For the ENET_ENHANCEDBUFFERDESCRIPTOR_MODE undefined use case, use the legacy type buffer descriptor transmit/receive the frame as follows.

Typical use case

```
enet_config_t config;
uint32_t length = 0;
uint32_t sysClock;
uint32_t phyAddr = 0;
bool link = false;
phy_speed_t speed;
phy_duplex_t duplex;
enet_status_t result;
enet_data_error_stats_t eErrorStatic;
// Prepares the buffer configuration.
enet_buffer_config_t buffCfg =
{
    ENET_RXBD_NUM,
    ENET_TXBD_NUM,
    ENET_BuffSizeAlign(ENET_RXBUFF_SIZE),
    ENET_BuffSizeAlign(ENET_TXBUFF_SIZE),
    &RxBuffDescrip[0],  // Prepare buffers
    &TxBuffDescrip[0],  // Prepare buffers
    &RxDataBuff[0][0],  // Prepare buffers
    &TxDataBuff[0][0],  // Prepare buffers
};

sysClock = CLOCK_GetFreq(kCLOCK_CoreSysClk);

// Gets the default configuration.
ENET_GetDefaultConfig(&config);
PHY_Init(EXAMPLE_ENET, 0, sysClock);
// Changes the link status to PHY auto-negotiated link status.
PHY_GetLinkStatus(EXAMPLE_ENET, phyAddr, &link);
if (link)
{
    PHY_GetLinkSpeedDuplex(EXAMPLE_ENET, phyAddr, &speed, &duplex);
    config.miiSpeed = (enet_mii_speed_t)speed;
    config.miiDuplex = (enet_mii_duplex_t)duplex;
}
ENET_Init(EXAMPLE_ENET, &handle, &config, &buffCfg, &macAddr[0], sysClock);
ENET_ActiveRead(EXAMPLE_ENET);

while (1)
{
    // Gets the frame size.
    result = ENET_GetRxFrameSize(&handle, &length);
    // Calls the ENET_ReadFrame when there is a received frame.
    if (length != 0)
    {
        // Receives a valid frame and delivers the receive buffer with the size equal to length.
        uint8_t *data = (uint8_t *)malloc(length);
        ENET_ReadFrame(EXAMPLE_ENET, &handle, data, length);
        // Delivers the data to the upper layer.
        .........
        free(data);
    }
    else if (result == kStatus_ENET_RxFrameErr)
    {
       // Updates the received buffer when an error occurs.
       ENET_GetRxErrBeforeReadFrame(&handle, &eErrStatic);
       // Updates the receive buffer.
       ENET_ReadFrame(EXAMPLE_ENET, &handle, NULL, 0);
    }

   // Sends a multicast frame when the PHY is linked up.
   if(kStatus_Success == PHY_GetLinkStatus(EXAMPLE_ENET, phyAddr, &link))
   {
      if(link)
      {
         ENET_SendFrame(EXAMPLE_ENET, &handle, &frame[0], ENET_DATA_LENGTH);
      }
  }
```

```
}
```

For the ENET_ENHANCEDBUFFERDESCRIPTOR_MODE defined use case, add the PTP IEEE 1588 configuration to enable the PTP IEEE 1588 feature. The initialization occurs as follows.

    &RxBuffDescrip[0],
    &TxBuffDescrip[0],
    &RxDataBuff[0][0],
    &TxDataBuff[0][0],
};

sysClock = CLOCK_GetFreq(kCLOCK_CoreSysClk);

// Sets the PTP 1588 source.

    &g_rxPtpTsBuff[0],
    &g_txPtpTsBuff[0],
    kENET_PtpTimerChannel1,
    ptpClock,
};

// Gets the default configuration.
ENET_GetDefaultConfig(&config);

PHY_Init(EXAMPLE_ENET, 0, sysClock);
// Changes the link status to PHY auto-negotiated link status.
PHY_GetLinkStatus(EXAMPLE_ENET, phyAddr, &link);
if (link)
{
    PHY_GetLinkSpeedDuplex(EXAMPLE_ENET, phyAddr, &speed, &duplex);

Note that for the internal DMA requirements, the buffers have a corresponding alignment requirements.

1. The aligned receive and transmit buffer size must be evenly divisible by ENET_BUFF_ALIGNMENT. when the data buffers are in cacheable region when cache is enabled, all those size should be aligned to the maximum value of "ENET_BUFF_ALIGNMENT" and the cache line size.
2. The aligned transmit and receive buffer descriptor start address must be at least 64 bit aligned. However, it's recommended to be evenly divisible by ENET_BUFF_ALIGNMENT. buffer descriptors should be put in non-cacheable region when cache is enabled.
3. The aligned transmit and receive data buffer start address must be evenly divisible by ENET_BUFF_ALIGNMENT. Receive buffers should be continuous with the total size equal to "rxBdNumber * rxBuffSizeAlign". Transmit buffers should be continuous with the total size equal to "txBdNumber * txBuffSizeAlign". when the data buffers are in cacheable region when cache is enabled, all those size should be aligned to the maximum value of "ENET_BUFF_ALIGNMENT" and the cache line

size.

2. txWatermark is used for a cut-through operation. It is in steps of 64 bytes. 0/1 - 64 bytes written to TX FIFO before transmission of a frame begins. 2 - 128 bytes written to TX FIFO .... 3 - 192 bytes written to TX FIFO .... The maximum of txWatermark is 0x2F - 4032 bytes written to TX FIFO. txWatermark allows minimizing the transmit latency to set the txWatermark to 0 or 1 or for larger

bus access latency 3 or larger due to contention for the system bus.

3. rxFifoFullThreshold is similar to the txWatermark for cut-through operation in RX. It is in 64-bit words. The minimum is ENET_FIFO_MIN_RX_FULL and the maximum is 0xFF. If the end of the frame is stored in FIFO and the frame size if smaller than the txWatermark, the frame is still transmitted. The rule is the same for rxFifoFullThreshold in the receive direction.
4. When "kENET_ControlFlowControlEnable" is set in the macSpecialConfig, ensure that the pauseDuration, rxFifoEmptyThreshold, and rxFifoStatEmptyThreshold are set for flow control enabled case.
5. When "kENET_ControlStoreAndFwdDisabled" is set in the macSpecialConfig, ensure that the rxFifoFullThreshold and txFifoWatermark are set for store and forward disable.
6. The rxAccelerConfig and txAccelerConfig default setting with 0 - accelerator are disabled. The "enet_tx_accelerator_t" and "enet_rx_accelerator_t" are recommended to be used to enable the transmit and receive accelerator. After the accelerators are enabled, the store and forward feature should be enabled. As a result, kENET_ControlStoreAndFwdDisabled should not be set.

13.7 Function Documentation

13.7.1 void ENET_GetDefaultConfig (enet_config_t * *config*)

The purpose of this API is to get the default ENET MAC controller configuration structure for ENET_-Init(). Users may use the initialized structure unchanged in ENET_Init() or modify fields of the structure before calling ENET_Init(). This is an example.

```
enet_config_t config;
ENET_GetDefaultConfig(&config);
```

Parameters

config	The ENET mac controller configuration structure pointer.

13.7.2 void ENET_Init (ENET_Type * *base*, enet_handle_t * *handle*, const enet_config_t * *config*, const enet_buffer_config_t * *bufferConfig*, uint8_t * *macAddr*, uint32_t *srcClock_Hz*)

This function ungates the module clock and initializes it with the ENET configuration.

Parameters

base	ENET peripheral base address.
handle	ENET handler pointer.
config	ENET Mac configuration structure pointer. The "enet_config_t" type mac configuration return from ENET_GetDefaultConfig can be used directly. It is also possible to verify the Mac configuration using other methods.
bufferConfig	ENET buffer configuration structure pointer. The buffer configuration should be prepared for ENET Initialization.
macAddr	ENET mac address of the Ethernet device. This Mac address should be provided.
srcClock_Hz	The internal module clock source for MII clock.

Note

ENET has two buffer descriptors legacy buffer descriptors and enhanced IEEE 1588 buffer descriptors. The legacy descriptor is used by default. To use the IEEE 1588 feature, use the enhanced IEEE 1588 buffer descriptor by defining "ENET_ENHANCEDBUFFERDESCRIPTOR_MODE" and calling ENET_Ptp1588Configure() to configure the 1588 feature and related buffers after calling ENET_Init().

This API must be called after the ENET_GetRxFrameSize and before the ENET_ReadFrame(). If the ENET_GetRxFrameSize returns kStatus_ENET_RxFrameError, the ENET_GetRxErrBeforeReadFrame can be used to get the exact error statistics. This is an example.

*           // Get the error information of the received frame.
*           ENET_GetRxErrBeforeReadFrame(&g_handle, &eErrStatic);
*           // update the receive buffer.

13.7.24 status_t ENET_GetRxFrameSize (enet_handle_t * *handle*, uint32_t * *length*)

This function gets a received frame size from the ENET buffer descriptors.

Note

The FCS of the frame is automatically removed by Mac and the size is the length without the FCS. After calling ENET_GetRxFrameSize, ENET_ReadFrame() should be called to update the receive buffers If the result is not "kStatus_ENET_RxFrameEmpty".

Parameters

handle	The ENET handler structure. This is the same handler pointer used in the ENET_Init.
length	The length of the valid frame received.

Return values

kStatus_ENET_RxFrame-Empty	No frame received. Should not call ENET_ReadFrame to read frame.

kStatus_Success	Receive a frame Successfully then the ENET_ReadFrame should be called with the right data buffer and the captured data length input.

13.7.25 status_t ENET_ReadFrame (ENET_Type * *base*, enet_handle_t * *handle*, uint8_t * *data*, uint32_t *length*)

This function reads a frame (both the data and the length) from the ENET buffer descriptors. The ENET-_GetRxFrameSize should be used to get the size of the prepared data buffer. This is an example.

```
*       uint32_t length;
*       enet_handle_t g_handle;
*       //Get the received frame size firstly.
*       status = ENET_GetRxFrameSize(&g_handle, &length);
```

```
*       if (length != 0)
*       {
*           //Allocate memory here with the size of "length"
*           uint8_t *data = memory allocate interface;
*           if (!data)
*           {
*               ENET_ReadFrame(ENET, &g_handle, NULL, 0);
*               //Add the console warning log.
*           }
*           else
*           {
*              status = ENET_ReadFrame(ENET, &g_handle, data, length);
*              //Call stack input API to deliver the data to stack
*           }
*       }
*       else if (status == kStatus_ENET_RxFrameError)
*       {
*          //Update the received buffer when a error frame is received.
*           ENET_ReadFrame(ENET, &g_handle, NULL, 0);
*       }
*
```

Parameters

handle	The ENET handler structure. This is the same handler pointer used in the ENET_Init.
data	The data buffer provided by user to store the frame which memory size should be at least "length".
length	The size of the data buffer which is still the length of the received frame.

Returns

The execute status, successful or failure.

13.7.26 status_t ENET_SendFrame (ENET_Type * *base*, enet_handle_t * *handle*, uint8_t * *data*, uint32_t *length*)

14.6 Function Documentation

14.6.1 void EWM_Init (EWM_Type * *base*, const ewm_config_t * *config*)

This function is used to initialize the EWM. After calling, the EWM runs immediately according to the configuration. Note that, except for the interrupt enable control bit, other control bits and registers are write once after a CPU reset. Modifying them more than once generates a bus transfer error.

This is an example.

```
*   ewm_config_t config;
*   EWM_GetDefaultConfig(&config);
*   config.compareHighValue = 0xAAU;
*   EWM_Init(ewm_base,&config);
*
```

Parameters

base	EWM peripheral base address
config	The configuration of the EWM

14.6.2 void EWM_Deinit (EWM_Type * *base*)

This function is used to shut down the EWM.

Parameters

base	EWM peripheral base address

14.6.3 void EWM_GetDefaultConfig (ewm_config_t * *config*)

This function initializes the EWM configuration structure to default values. The default values are as follows.

```
*   ewmConfig->enableEwm = true;
*   ewmConfig->enableEwmInput = false;
*   ewmConfig->setInputAssertLogic = false;
```

```
*   ewmConfig->enableInterrupt = false;
*   ewmConfig->ewm_lpo_clock_source_t = kEWM_LpoClockSource0;
*   ewmConfig->prescaler = 0;
*   ewmConfig->compareLowValue = 0;
*   ewmConfig->compareHighValue = 0xFEU;
*
```

Parameters

config	Pointer to the EWM configuration structure.

*   status = EWM_GetStatusFlags(ewm_base) & kEWM_RunningFlag;
*
```

Chapter 16
FlexBus: External Bus Interface Driver

16.1 Overview

The MCUXpresso SDK provides a peripheral driver for the Crossbar External Bus Interface (FlexBus) block of MCUXpresso SDK devices.

A multifunction external bus interface is provided on the device with a basic functionality to interface to slave-only devices. It can be directly connected to the following asynchronous or synchronous devices with little or no additional circuitry.

- External ROMs
- Flash memories
- Programmable logic devices
- Other simple target (slave) devices

For asynchronous devices, a simple chip-select based interface can be used. The FlexBus interface has up to six general purpose chip-selects, FB_CS[5:0]. The number of chip selects available depends on the device and its pin configuration.

16.2 FlexBus functional operation

To configure the FlexBus driver, use on of the two ways to configure the flexbus_config_t structure.

1. Using the FLEXBUS_GetDefaultConfig() function.
2. Set parameters in the flexbus_config_t structure.

To initialize and configure the FlexBus driver, call the FLEXBUS_Init() function and pass a pointer to the flexbus_config_t structure.

To de-initialize the FlexBus driver, call the FLEXBUS_Deinit() function.

16.3 Typical use case and example

This example shows how to write/read to external memory (MRAM) by using the FlexBus module.

```
flexbus_config_t flexbusUserConfig;

FLEXBUS_GetDefaultConfig(&flexbusUserConfig); /* Gets the default configuration. */
/* Configure some parameters when using MRAM */
flexbusUserConfig.waitStates            = 2U;                /* Wait 2 states */
flexbusUserConfig.chipBaseAddress       = MRAM_START_ADDRESS; /* MRAM address for using
       FlexBus */
flexbusUserConfig.chipBaseAddressMask   = 7U;                /* 512 kilobytes memory
       size */
FLEXBUS_Init(FB, &flexbusUserConfig); /* Initializes and configures the FlexBus module */

/* Do something */

FLEXBUS_Deinit(FB);
```

17.2.5 Typedef Documentation

17.2.5.1 typedef void(∗ flexcan_transfer_callback_t)(CAN_Type ∗base, flexcan_handle_t ∗handle, status_t status, uint32_t result, void ∗userData)

The FlexCAN transfer callback returns a value from the underlying layer. If the status equals to kStatus-_FLEXCAN_ErrorStatus, the result parameter is the Content of FlexCAN status register which can be used to get the working status(or error status) of FlexCAN module. If the status equals to other FlexCAN Message Buffer transfer status, the result is the index of Message Buffer that generate transfer event. If the status equals to other FlexCAN Message Buffer transfer status, the result is meaningless and should be Ignored.

Chapter 18
FTM: FlexTimer Driver

18.1 Overview

The MCUXpresso SDK provides a driver for the FlexTimer Module (FTM) of MCUXpresso SDK devices.

18.2 Function groups

The FTM driver supports the generation of PWM signals, input capture, dual edge capture, output compare, and quadrature decoder modes. The driver also supports configuring each of the FTM fault inputs.

18.2.1 Initialization and deinitialization

The function FTM_Init() initializes the FTM with specified configurations. The function FTM_GetDefaultConfig() gets the default configurations. The initialization function configures the FTM for the requested register update mode for registers with buffers. It also sets up the FTM's fault operation mode and FTM behavior in the BDM mode.

The function FTM_Deinit() disables the FTM counter and turns off the module clock.

18.2.2 PWM Operations

The function FTM_SetupPwm() sets up FTM channels for the PWM output. The function sets up the PWM signal properties for multiple channels. Each channel has its own duty cycle and level-mode specified. However, the same PWM period and PWM mode is applied to all channels requesting the PWM output. The signal duty cycle is provided as a percentage of the PWM period. Its value should be between 0 and 100 0=inactive signal (0% duty cycle) and 100=always active signal (100% duty cycle).

The function FTM_UpdatePwmDutycycle() updates the PWM signal duty cycle of a particular FTM channel.

The function FTM_UpdateChnlEdgeLevelSelect() updates the level select bits of a particular FTM channel. This can be used to disable the PWM output when making changes to the PWM signal.

18.2.3 Input capture operations

The function FTM_SetupInputCapture() sets up an FTM channel for the input capture. The user can specify the capture edge and a filter value to be used when processing the input signal.

The function FTM_SetupDualEdgeCapture() can be used to measure the pulse width of a signal. A channel pair is used during capture with the input signal coming through a channel n. The user can specify whether

to use one-shot or continuous capture, the capture edge for each channel, and any filter value to be used when processing the input signal.

18.2.4 Output compare operations

The function FTM_SetupOutputCompare() sets up an FTM channel for the output comparison. The user can specify the channel output on a successful comparison and a comparison value.

18.2.5 Quad decode

The function FTM_SetupQuadDecode() sets up FTM channels 0 and 1 for quad decoding. The user can specify the quad decoding mode, polarity, and filter properties for each input signal.

18.2.6 Fault operation

The function FTM_SetupFault() sets up the properties for each fault. The user can specify the fault polarity and whether to use a filter on a fault input. The overall fault filter value and fault control mode are set up during initialization.

18.3 Register Update

Some of the FTM registers have buffers. The driver supports various methods to update these registers with the content of the register buffer. The registers can be updated using the PWM synchronized loading or an intermediate point loading. The update mechanism for register with buffers can be specified through the following fields available in the configuration structure.

```
uint32_t pwmSyncMode;
uint32_t reloadPoints;
```

Multiple PWM synchronization update modes can be used by providing an OR'ed list of options available in the enumeration ftm_pwm_sync_method_t to the pwmSyncMode field.

When using an intermediate reload points, the PWM synchnronization is not required. Multiple reload points can be used by providing an OR'ed list of options available in the enumeration ftm_reload_point_t to the reloadPoints field.

The driver initialization function sets up the appropriate bits in the FTM module based on the register update options selected.

If software PWM synchronization is used, the below function can be used to initiate a software trigger.

```
FTM_SetSoftwareTrigger(FTM0, true)
```

18.4 Typical use case

18.4.1 PWM output

Output a PWM signal on two FTM channels with different duty cycles. Periodically update the PWM signal duty cycle.

```
int main(void)
{
    bool brightnessUp = true; /* Indicates whether LEDs are brighter or dimmer. */
    ftm_config_t ftmInfo;
    uint8_t updatedDutycycle = 0U;
    ftm_chnl_pwm_signal_param_t ftmParam[2];

    /* Configures the FTM parameters with frequency 24 kHZ */
    ftmParam[0].chnlNumber = (ftm_chnl_t)BOARD_FIRST_FTM_CHANNEL;
    ftmParam[0].level = kFTM_LowTrue;
    ftmParam[0].dutyCyclePercent = 0U;
    ftmParam[0].firstEdgeDelayPercent = 0U;

    ftmParam[1].chnlNumber = (ftm_chnl_t)BOARD_SECOND_FTM_CHANNEL;
    ftmParam[1].level = kFTM_LowTrue;
    ftmParam[1].dutyCyclePercent = 0U;
    ftmParam[1].firstEdgeDelayPercent = 0U;

    FTM_GetDefaultConfig(&ftmInfo);

    /* Initializes the FTM module. */
    FTM_Init(BOARD_FTM_BASEADDR, &ftmInfo);

    FTM_SetupPwm(BOARD_FTM_BASEADDR, ftmParam, 2U,
      kFTM_EdgeAlignedPwm, 24000U, FTM_SOURCE_CLOCK);
    FTM_StartTimer(BOARD_FTM_BASEADDR, kFTM_SystemClock);

    while (1)
    {
        /* Delays to check whether the LED brightness has changed. */
        delay();

        if (brightnessUp)
        {
            /* Increases the duty cycle until it reaches a limited value. */
            if (++updatedDutycycle == 100U)
            {
                brightnessUp = false;
            }
        }
        else
        {
            /* Decreases the duty cycle until it reaches a limited value. */
            if (--updatedDutycycle == 0U)
            {
                brightnessUp = true;
            }
        }
        /* Starts the PWM mode with an updated duty cycle. */
        FTM_UpdatePwmDutycycle(BOARD_FTM_BASEADDR, (
      ftm_chnl_t)BOARD_FIRST_FTM_CHANNEL, kFTM_EdgeAlignedPwm,
                               updatedDutycycle);
        FTM_UpdatePwmDutycycle(BOARD_FTM_BASEADDR, (
      ftm_chnl_t)BOARD_SECOND_FTM_CHANNEL, kFTM_EdgeAlignedPwm,
                               updatedDutycycle);
        /* Software trigger to update registers. */
        FTM_SetSoftwareTrigger(BOARD_FTM_BASEADDR, true);
    }
}

19.5.3 Function Documentation

19.5.3.1 void GPIO_PinInit (GPIO_Type ∗ *base*, uint32_t *pin*, const gpio_pin_config_t ∗ *config*)

To initialize the GPIO, define a pin configuration, as either input or output, in the user file. Then, call the GPIO_PinInit() function.

This is an example to define an input pin or an output pin configuration.

```
* // Define a digital input pin configuration,
* gpio_pin_config_t config =
* {
*   kGPIO_DigitalInput,
*   0,
* }
* //Define a digital output pin configuration,
* gpio_pin_config_t config =
* {
*   kGPIO_DigitalOutput,
*   0,
* }
*
```

Parameters

base	GPIO peripheral base pointer (GPIOA, GPIOB, GPIOC, and so on.)
pin	GPIO port pin number
config	GPIO pin configuration pointer

19.5.3.2 static void GPIO_WritePinOutput (GPIO_Type ∗ *base*, uint32_t *pin*, uint8_t *output*) [inline], [static]

Parameters

base	GPIO peripheral base pointer (GPIOA, GPIOB, GPIOC, and so on.)
pin	GPIO pin number
output	GPIO pin output logic level. • 0: corresponding pin output low-logic level. • 1: corresponding pin output high-logic level.

19.5.3.3 static void GPIO_SetPinsOutput (GPIO_Type * *base,* uint32_t *mask*) [inline], [static]

Parameters

base	GPIO peripheral base pointer (GPIOA, GPIOB, GPIOC, and so on.)
mask	GPIO pin number macro

19.5.3.4 static void GPIO_ClearPinsOutput (GPIO_Type * *base,* uint32_t *mask*) [inline], [static]

Parameters

base	GPIO peripheral base pointer (GPIOA, GPIOB, GPIOC, and so on.)
mask	GPIO pin number macro

19.5.3.5 static void GPIO_TogglePinsOutput (GPIO_Type * *base,* uint32_t *mask*) [inline], [static]

Parameters

base	GPIO peripheral base pointer (GPIOA, GPIOB, GPIOC, and so on.)
mask	GPIO pin number macro

19.5.3.6 static uint32_t GPIO_ReadPinInput (GPIO_Type * *base,* uint32_t *pin*) [inline], [static]

Parameters

base	GPIO peripheral base pointer (GPIOA, GPIOB, GPIOC, and so on.)
pin	GPIO pin number

Return values

GPIO	port input value • 0: corresponding pin input low-logic level. • 1: corresponding pin input high-logic level.

19.5.3.7 uint32_t GPIO_GetPinsInterruptFlags (GPIO_Type * *base*)

If a pin is configured to generate the DMA request, the corresponding flag is cleared automatically at the completion of the requested DMA transfer. Otherwise, the flag remains set until a logic one is written to that flag. If configured for a level sensitive interrupt that remains asserted, the flag is set again immediately.

Parameters

base	GPIO peripheral base pointer (GPIOA, GPIOB, GPIOC, and so on.)

Return values

The	current GPIO port interrupt status flag, for example, 0x00010001 means the pin 0 and 17 have the interrupt.

Parameters

base	GPIO peripheral base pointer (GPIOA, GPIOB, GPIOC, and so on.)
mask	GPIO pin number macro

19.6 FGPIO Driver

This chapter describes the programming interface of the FGPIO driver. The FGPIO driver configures the FGPIO module and provides a functional interface to build the GPIO application.

Note

FGPIO (Fast GPIO) is only available in a few MCUs. FGPIO and GPIO share the same peripheral but use different registers. FGPIO is closer to the core than the regular GPIO and it's faster to read and write.

19.6.1 Typical use case

19.6.1.1 Output Operation

```
/* Output pin configuration */
gpio_pin_config_t led_config =
{
    kGpioDigitalOutput,
    1,
};
/*  Sets the configuration */
FGPIO_PinInit(FGPIO_LED, LED_PINNUM, &led_config);
```

19.6.1.2 Input Operation

```
/*  Input pin configuration */
PORT_SetPinInterruptConfig(BOARD_SW2_PORT, BOARD_SW2_FGPIO_PIN,
      kPORT_InterruptFallingEdge);
NVIC_EnableIRQ(BOARD_SW2_IRQ);
gpio_pin_config_t sw1_config =
{
    kGpioDigitalInput,
    0,
};
/* Sets the input pin configuration */
FGPIO_PinInit(FGPIO_SW1, SW1_PINNUM, &sw1_config);
```

20.2 I2C Driver

20.2.1 Overview

The MCUXpresso SDK provides a peripheral driver for the Inter-Integrated Circuit (I2C) module of MCUXpresso SDK devices.

The I2C driver includes functional APIs and transactional APIs.

Functional APIs target the low-level APIs. Functional APIs can be used for the I2C master/slave initialization/configuration/operation for optimization/customization purpose. Using the functional APIs requires knowing the I2C master peripheral and how to organize functional APIs to meet the application requirements. The I2C functional operation groups provide the functional APIs set.

Transactional APIs target the high-level APIs. The transactional APIs can be used to enable the peripheral quickly and also in the application if the code size and performance of transactional APIs satisfy the requirements. If the code size and performance are critical requirements, see the transactional API implementation and write custom code using the functional APIs or accessing the hardware registers.

Transactional APIs support asynchronous transfer. This means that the functions I2C_MasterTransferNonBlocking() set up the interrupt non-blocking transfer. When the transfer completes, the upper layer is notified through a callback function with the status.

20.2.2 Typical use case

20.2.7 Function Documentation

20.2.7.1 void I2C_MasterInit (I2C_Type * *base*, const i2c_master_config_t * *masterConfig*, uint32_t *srcClock_Hz*)

Call this API to ungate the I2C clock and configure the I2C with master configuration.

This is an example.

```
* i2c_master_config_t config = {
* .enableMaster = true,
* .enableStopHold = false,
* .highDrive = false,
* .baudRate_Bps = 100000,
* .glitchFilterWidth = 0

20.2.7.31 status_t I2C_SlaveTransferNonBlocking (I2C_Type * *base*, i2c_slave_handle_t * *handle*, uint32_t *eventMask*)

Call this API after calling the I2C_SlaveInit() and I2C_SlaveTransferCreateHandle() to start processing transactions driven by an I2C master. The slave monitors the I2C bus and passes events to the callback

that was passed into the call to I2C_SlaveTransferCreateHandle(). The callback is always invoked from the interrupt context.

The set of events received by the callback is customizable. To do so, set the *eventMask* parameter to the OR'd combination of i2c_slave_transfer_event_t enumerators for the events you wish to receive. The kI2C_SlaveTransmitEvent and #kLPI2C_SlaveReceiveEvent events are always enabled and do not need to be included in the mask. Alternatively, pass 0 to get a default set of only the transmit and receive events that are always enabled. In addition, the kI2C_SlaveAllEvents constant is provided as a convenient way to enable all events.

Parameters

base	The I2C peripheral base address.
handle	Pointer to #i2c_slave_handle_t structure which stores the transfer state.
eventMask	Bit mask formed by OR'ing together i2c_slave_transfer_event_t enumerators to specify which events to send to the callback. Other accepted values are 0 to get a default set of only the transmit and receive events, and kI2C_SlaveAllEvents to enable all events.

Return values

#kStatus_Success	Slave transfers were successfully started.
kStatus_I2C_Busy	Slave transfers have already been started on this handle.

Chapter 22
LPTMR: Low-Power Timer

22.1 Overview

The MCUXpresso SDK provides a driver for the Low-Power Timer (LPTMR) of MCUXpresso SDK devices.

22.2 Function groups

The LPTMR driver supports operating the module as a time counter or as a pulse counter.

22.2.1 Initialization and deinitialization

The function LPTMR_Init() initializes the LPTMR with specified configurations. The function LPTMR_GetDefaultConfig() gets the default configurations. The initialization function configures the LPTMR for a timer or a pulse counter mode mode. It also sets up the LPTMR's free running mode operation and a clock source.

The function LPTMR_DeInit() disables the LPTMR module and gates the module clock.

22.2.2 Timer period Operations

The function LPTMR_SetTimerPeriod() sets the timer period in units of count. Timers counts from 0 to the count value set here.

The function LPTMR_GetCurrentTimerCount() reads the current timer counting value. This function returns the real-time timer counting value ranging from 0 to a timer period.

The timer period operation function takes the count value in ticks. Call the utility macros provided in the fsl_common.h file to convert to microseconds or milliseconds.

22.2.3 Start and Stop timer operations

The function LPTMR_StartTimer() starts the timer counting. After calling this function, the timer counts up to the counter value set earlier by using the LPTMR_SetPeriod() function. Each time the timer reaches the count value and increments, it generates a trigger pulse and sets the timeout interrupt flag. An interrupt is also triggered if the timer interrupt is enabled.

The function LPTMR_StopTimer() stops the timer counting and resets the timer's counter register.

22.2.4 Status

Provides functions to get and clear the LPTMR status.

22.2.5 Interrupt

Provides functions to enable/disable LPTMR interrupts and get the currently enabled interrupts.

22.3 Typical use case

22.3.1 LPTMR tick example

Updates the LPTMR period and toggles an LED periodically.

```
int main(void)
{
    uint32_t currentCounter = 0U;
    lptmr_config_t lptmrConfig;

    LED_INIT();

    /* Board pin, clock, debug console initialization */
    BOARD_InitHardware();

    /* Configures the LPTMR */
    LPTMR_GetDefaultConfig(&lptmrConfig);

    /* Initializes the LPTMR */
    LPTMR_Init(LPTMR0, &lptmrConfig);

    /* Sets the timer period */
    LPTMR_SetTimerPeriod(LPTMR0, USEC_TO_COUNT(1000000U, LPTMR_SOURCE_CLOCK));

    /* Enables a timer interrupt */
    LPTMR_EnableInterrupts(LPTMR0,
      kLPTMR_TimerInterruptEnable);

    /* Enables the NVIC */
    EnableIRQ(LPTMR0_IRQn);

    PRINTF("Low Power Timer Example\r\n");

    /* Starts counting */
    LPTMR_StartTimer(LPTMR0);
    while (1)
    {
        if (currentCounter != lptmrCounter)
        {
            currentCounter = lptmrCounter;
            PRINTF("LPTMR interrupt No.%d \r\n", currentCounter);
        }
    }
}

Chapter 23
PDB: Programmable Delay Block

23.1 Overview

The MCUXpresso SDK provides a peripheral driver for the Programmable Delay Block (PDB) module of MCUXpresso SDK devices.

The PDB driver includes a basic PDB counter, trigger generators for ADC, DAC, and pulse-out.

The basic PDB counter can be used as a general programmable timer with an interrupt. The counter increases automatically with the divided clock signal after it is triggered to start by an external trigger input or the software trigger. There are "milestones" for the output trigger event. When the counter is equal to any of these "milestones", the corresponding trigger is generated and sent out to other modules. These "milestones" are for the following events.

- Counter delay interrupt, which is the interrupt for the PDB module
- ADC pre-trigger to trigger the ADC conversion
- DAC interval trigger to trigger the DAC buffer and move the buffer read pointer
- Pulse-out triggers to generate a single of rising and falling edges, which can be assembled to a window.

The "milestone" values have a flexible load mode. To call the APIs to set these value is equivalent to writing data to their buffer. The loading event occurs as the load mode describes. This design ensures that all "milestones" can be updated at the same time.

23.2 Typical use case

23.2.1 Working as basic PDB counter with a PDB interrupt.

```
int main(void)
{
    // ...
    EnableIRQ(DEMO_PDB_IRQ_ID);

    // ...
    // Configures the PDB counter.
    PDB_GetDefaultConfig(&pdbConfigStruct);
    PDB_Init(DEMO_PDB_INSTANCE, &pdbConfigStruct);

    // Configures the delay interrupt.
    PDB_SetModulusValue(DEMO_PDB_INSTANCE, 1000U);
    PDB_SetCounterDelayValue(DEMO_PDB_INSTANCE, 1000U); // The available delay
       value is less than or equal to the modulus value.
    PDB_EnableInterrupts(DEMO_PDB_INSTANCE,
      kPDB_DelayInterruptEnable);
    PDB_DoLoadValues(DEMO_PDB_INSTANCE);

    while (1)
    {
        // ...
        g_PdbDelayInterruptFlag = false;
```

```
        PDB_DoSoftwareTrigger(DEMO_PDB_INSTANCE);
        while (!g_PdbDelayInterruptFlag)
        {
        }
    }
 }

{

    PDB_ClearStatusFlags(DEMO_PDB_INSTANCE,

}
```

23.2.2 Working with an additional trigger. The ADC trigger is used as an example.

    ADC16_SetChannelConfig(DEMO_PDB_ADC_INSTANCE, DEMO_PDB_ADC_CHANNEL_GROUP, &
      adc16ChannelConfigStruct);
}

{
    uint32_t tmp32;

    g_AdcInterruptCounter++;
    g_AdcInterruptFlag = true;
}

int main(void)
{

Chapter 24
PIT: Periodic Interrupt Timer

24.1 Overview

The MCUXpresso SDK provides a driver for the Periodic Interrupt Timer (PIT) of MCUXpresso SDK devices.

24.2 Function groups

The PIT driver supports operating the module as a time counter.

24.2.1 Initialization and deinitialization

The function PIT_Init() initializes the PIT with specified configurations. The function PIT_GetDefaultConfig() gets the default configurations. The initialization function configures the PIT operation in debug mode.

The function PIT_SetTimerChainMode() configures the chain mode operation of each PIT channel.

The function PIT_Deinit() disables the PIT timers and disables the module clock.

24.2.2 Timer period Operations

The function PITR_SetTimerPeriod() sets the timer period in units of count. Timers begin counting down from the value set by this function until it reaches 0.

The function PIT_GetCurrentTimerCount() reads the current timer counting value. This function returns the real-time timer counting value, in a range from 0 to a timer period.

The timer period operation functions takes the count value in ticks. Users can call the utility macros provided in fsl_common.h to convert to microseconds or milliseconds.

24.2.3 Start and Stop timer operations

The function PIT_StartTimer() starts the timer counting. After calling this function, the timer loads the period value set earlier via the PIT_SetPeriod() function and starts counting down to 0. When the timer reaches 0, it generates a trigger pulse and sets the timeout interrupt flag.

The function PIT_StopTimer() stops the timer counting.

24.2.4 Status

Provides functions to get and clear the PIT status.

24.2.5 Interrupt

Provides functions to enable/disable PIT interrupts and get current enabled interrupts.

24.3 Typical use case

24.3.1 PIT tick example

Updates the PIT period and toggles an LED periodically.

```
int main(void)
{
    /* Structure of initialize PIT */
    pit_config_t pitConfig;

    /* Initialize and enable LED */
    LED_INIT();

    /* Board pin, clock, debug console init */
    BOARD_InitHardware();

    PIT_GetDefaultConfig(&pitConfig);

    /* Init pit module */
    PIT_Init(PIT, &pitConfig);

    /* Set timer period for channel 0 */
    PIT_SetTimerPeriod(PIT, kPIT_Chnl_0, USEC_TO_COUNT(1000000U,
      PIT_SOURCE_CLOCK));

    /* Enable timer interrupts for channel 0 */
    PIT_EnableInterrupts(PIT, kPIT_Chnl_0,
      kPIT_TimerInterruptEnable);

    /* Enable at the NVIC */
    EnableIRQ(PIT_IRQ_ID);

    /* Start channel 0 */
    PRINTF("\r\nStarting channel No.0 ...");
    PIT_StartTimer(PIT, kPIT_Chnl_0);

    while (true)
    {
        /* Check whether occur interupt and toggle LED */
        if (true == pitIsrFlag)
        {
            PRINTF("\r\n Channel No.0 interrupt is occured !");
            LED_TOGGLE();
            pitIsrFlag = false;
        }
    }
}
```

24.6 Function Documentation

24.6.1 void PIT_Init (PIT_Type * *base*, const pit_config_t * *config*)

Note

This API should be called at the beginning of the application using the PIT driver.

Parameters

base	PIT peripheral base address
config	Pointer to the user's PIT config structure

24.6.2 void PIT_Deinit (PIT_Type * *base*)

Parameters

base	PIT peripheral base address

24.6.3 static void PIT_GetDefaultConfig (pit_config_t * *config*) [inline], [static]

The default values are as follows.

```
*     config->enableRunInDebug = false;
*
```

Parameters

config	Pointer to the onfiguration structure.

24.6.4 static void PIT_SetTimerChainMode (PIT_Type * *base*, pit_chnl_t *channel*, bool *enable*) [inline], [static]

When a timer has a chain mode enabled, it only counts after the previous timer has expired. If the timer n-1 has counted down to 0, counter n decrements the value by one. Each timer is 32-bits, which allows the developers to chain timers together and form a longer timer (64-bits and larger). The first timer (timer 0) can't be chained to any other timer.

Parameters

base	PIT peripheral base address
channel	Timer channel number which is chained with the previous timer
enable	Enable or disable chain. true: Current timer is chained with the previous timer. false: Timer doesn't chain with other timers.

24.6.5 static void PIT_EnableInterrupts (PIT_Type * *base*, pit_chnl_t *channel*, uint32_t *mask*) [inline], [static]

Parameters

base	PIT peripheral base address
channel	Timer channel number
mask	The interrupts to enable. This is a logical OR of members of the enumeration pit_interrupt_enable_t

24.6.10 static void PIT_SetTimerPeriod (PIT_Type * *base*, pit_chnl_t *channel*, uint32_t *count*) [inline], [static]

Timers begin counting from the value set by this function until it reaches 0, then it generates an interrupt and load this register value again. Writing a new value to this register does not restart the timer. Instead, the value is loaded after the timer expires.

Note

Users can call the utility macros provided in fsl_common.h to convert to ticks.

Parameters

base	PIT peripheral base address
channel	Timer channel number
count	Timer period in units of ticks

24.6.11 static uint32_t PIT_GetCurrentTimerCount (PIT_Type * *base*, pit_chnl_t *channel*) [inline], [static]

Note

Users can call the utility macros provided in fsl_common.h to convert ticks to usec or msec.

Parameters

base	PIT peripheral base address
channel	Timer channel number

Returns

Current timer counting value in ticks

24.6.12 static void PIT_StartTimer (PIT_Type * *base,* pit_chnl_t *channel*) [inline], [static]

After calling this function, timers load period value, count down to 0 and then load the respective start value again. Each time a timer reaches 0, it generates a trigger pulse and sets the timeout interrupt flag.

Parameters

base	PIT peripheral base address
channel	Timer channel number.

24.6.13 static void PIT_StopTimer (PIT_Type * *base,* pit_chnl_t *channel*) [inline], [static]

This function stops every timer counting. Timers reload their periods respectively after the next time they call the PIT_DRV_StartTimer.

Parameters

base	PIT peripheral base address
channel	Timer channel number.

Chapter 28
RNGA: Random Number Generator Accelerator Driver

28.1 Overview

The MCUXpresso SDK provides Peripheral driver for the Random Number Generator Accelerator (RNGA) block of MCUXpresso SDK devices.

28.2 RNGA Initialization

1. To initialize the RNGA module, call the RNGA_Init() function. This function automatically enables the RNGA module and its clock.
2. After calling the RNGA_Init() function, the RNGA is enabled and the counter starts working.
3. To disable the RNGA module, call the RNGA_Deinit() function.

28.3 Get random data from RNGA

1. RNGA_GetRandomData() function gets random data from the RNGA module.

28.4 RNGA Set/Get Working Mode

The RNGA works either in sleep mode or normal mode

1. RNGA_SetMode() function sets the RNGA mode.
2. RNGA_GetMode() function gets the RNGA working mode.

28.5 Seed RNGA

1. RNGA_Seed() function inputs an entropy value that the RNGA can use to seed the pseudo random algorithm.

This example code shows how to initialize and get random data from the RNGA driver:

```
{
    status_t       status;
    uint32_t       data;

    /* Initialize RNGA */
    status = RNGA_Init(RNG);

    /* Read Random data*/
    status = RNGA_GetRandomData(RNG, data, sizeof(data));

    if(status == kStatus_Success)
    {
        /* Print data*/
        PRINTF("Random = 0x%X\r\n", i, data );
        PRINTF("Succeed.\r\n");
    }
    else
    {
```

```
        PRINTF("RNGA failed! (0x%x)\r\n", status);
    }

    /* Deinitialize RNGA*/
    RNGA_Deinit(RNG);
}
```

Note

It is important to note that there is no known cryptographic proof showing this is a secure method for generating random data. In fact, there may be an attack against this random number generator if its output is used directly in a cryptographic application. The attack is based on the linearity of the internal shift registers. Therefore, it is highly recommended that the random data produced by this module be used as an entropy source to provide an input seed to a NIST-approved pseudo-random-number generator based on DES or SHA-1 and defined in NIST FIPS PUB 186-2 Appendix 3 and NIST FIPS PUB SP 800-90. The requirement is needed to maximize the entropy of this input seed. To do this, when data is extracted from RNGA as quickly as the hardware allows, there are one to two bits of added entropy per 32-bit word. Any single bit of that word contains that entropy. Therefore, when used as an entropy source, a random number should be generated for each bit of entropy required and the least significant bit (any bit would be equivalent) of each word retained. The remainder of each random number should then be discarded. Used this way, even with full knowledge of the internal state of RNGA and all prior random numbers, an attacker is not able to predict the values of the extracted bits. Other sources of entropy can be used along with RNGA to generate the seed to the pseudorandom algorithm. The more random sources combined to create the seed, the better. The following is a list of sources that can be easily combined with the output of this module.

- Current time using highest precision possible
- Real-time system inputs that can be characterized as "random"
- Other entropy supplied directly by the user

Chapter 29
RTC: Real Time Clock

29.1 Overview

The MCUXpresso SDK provides a driver for the Real Time Clock (RTC) of MCUXpresso SDK devices.

29.2 Function groups

The RTC driver supports operating the module as a time counter.

29.2.1 Initialization and deinitialization

The function RTC_Init() initializes the RTC with specified configurations. The function RTC_GetDefaultConfig() gets the default configurations.

The function RTC_Deinit() disables the RTC timer and disables the module clock.

29.2.2 Set & Get Datetime

The function RTC_SetDatetime() sets the timer period in seconds. Users pass in the details in date & time format by using the below data structure.

```
typedef struct _rtc_datetime
{
    uint16_t year;
    uint8_t month;
    uint8_t day;
    uint8_t hour;
    uint8_t minute;
    uint8_t second;
} rtc_datetime_t;
```

The function RTC_GetDatetime() reads the current timer value in seconds, converts it to date & time format and stores it into a datetime structure passed in by the user.

29.2.3 Set & Get Alarm

The function RTC_SetAlarm() sets the alarm time period in seconds. Users pass in the details in date & time format by using the datetime data structure.

The function RTC_GetAlarm() reads the alarm time in seconds, converts it to date & time format and stores it into a datetime structure passed in by the user.

29.2.4 Start & Stop timer

The function RTC_StartTimer() starts the RTC time counter.

The function RTC_StopTimer() stops the RTC time counter.

29.2.5 Status

Provides functions to get and clear the RTC status.

29.2.6 Interrupt

Provides functions to enable/disable RTC interrupts and get current enabled interrupts.

29.2.7 RTC Oscillator

Some SoC's allow control of the RTC oscillator through the RTC module.

The function RTC_SetOscCapLoad() allows the user to modify the capacitor load configuration of the RTC oscillator.

29.2.8 Monotonic Counter

Some SoC's have a 64-bit Monotonic counter available in the RTC module.

The function RTC_SetMonotonicCounter() writes a 64-bit to the counter.

The function RTC_GetMonotonicCounter() reads the monotonic counter and returns the 64-bit counter value to the user.

The function RTC_IncrementMonotonicCounter() increments the Monotonic Counter by one.

Chapter 30
SAI: Serial Audio Interface

30.1 Overview

The MCUXpresso SDK provides a peripheral driver for the Serial Audio Interface (SAI) module of MCUXpresso SDK devices.

SAI driver includes functional APIs and transactional APIs.

Functional APIs target low-level APIs. Functional APIs can be used for SAI initialization, configuration and operation, and for optimization and customization purposes. Using the functional API requires the knowledge of the SAI peripheral and how to organize functional APIs to meet the application requirements. All functional API use the peripheral base address as the first parameter. SAI functional operation groups provide the functional API set.

Transactional APIs target high-level APIs. Transactional APIs can be used to enable the peripheral and in the application if the code size and performance of transactional APIs satisfy the requirements. If the code size and performance are a critical requirement, see the transactional API implementation and write a custom code. All transactional APIs use the sai_handle_t as the first parameter. Initialize the handle by calling the SAI_TransferTxCreateHandle() or SAI_TransferRxCreateHandle() API.

Transactional APIs support asynchronous transfer. This means that the functions SAI_TransferSendNonBlocking() and SAI_TransfferReceiveNonBlocking() set up the interrupt for data transfer. When the transfer completes, the upper layer is notified through a callback function with the kStatus_SAI_TxIdle and kStatus_SAI_RxIdle status.

30.2 Typical use case

30.2.1 SAI Send/receive using an interrupt method

```
sai_handle_t g_saiTxHandle;
sai_config_t user_config;
sai_transfer_t sendXfer;
volatile bool txFinished;
volatile bool rxFinished;
const uint8_t sendData[] = [......];

void SAI_UserCallback(sai_handle_t *handle, status_t status, void *userData)
{
    userData = userData;

    if (kStatus_SAI_TxIdle == status)
    {
        txFinished = true;
    }
}

void main(void)
{
    //...
```

```
    SAI_TxGetDefaultConfig(&user_config);

    SAI_TxInit(SAI0, &user_config);
    SAI_TransferTxCreateHandle(SAI0, &g_saiHandle, SAI_UserCallback, NULL);

    //Configure sai format
    SAI_TransferTxSetTransferFormat(SAI0, &g_saiHandle, mclkSource, mclk);

    // Prepare to send.
    sendXfer.data = sendData
    sendXfer.dataSize = sizeof(sendData)/sizeof(sendData[0]);
    txFinished = false;

    // Send out.
    SAI_TransferSendNonBlocking(SAI0, &g_saiHandle, &sendXfer);

    // Wait send finished.
    while (!txFinished)
    {
    }

    // ...
}
```

30.2.2 SAI Send/receive using a DMA method

```
sai_handle_t g_saiHandle;
dma_handle_t g_saiTxDmaHandle;
dma_handle_t g_saiRxDmaHandle;
sai_config_t user_config;
sai_transfer_t sendXfer;
volatile bool txFinished;
uint8_t sendData[] = ...;

void SAI_UserCallback(sai_handle_t *handle, status_t status, void *userData)
{
    userData = userData;

    if (kStatus_SAI_TxIdle == status)
    {
        txFinished = true;
    }
}

void main(void)
{
    //...

    SAI_TxGetDefaultConfig(&user_config);
    SAI_TxInit(SAI0, &user_config);

    // Sets up the DMA.
    DMAMUX_Init(DMAMUX0);
    DMAMUX_SetSource(DMAMUX0, SAI_TX_DMA_CHANNEL, SAI_TX_DMA_REQUEST);
    DMAMUX_EnableChannel(DMAMUX0, SAI_TX_DMA_CHANNEL);

    DMA_Init(DMA0);

    /* Creates the DMA handle. */
    DMA_CreateHandle(&g_saiTxDmaHandle, DMA0, SAI_TX_DMA_CHANNEL);

    SAI_TransferTxCreateHandleDMA(SAI0, &g_saiTxDmaHandle, SAI_UserCallback,
      NULL);

    // Prepares to send.
```

```
    sendXfer.data = sendData
    sendXfer.dataSize = sizeof(sendData)/sizeof(sendData[0]);
    txFinished = false;

    // Sends out.
    SAI_TransferSendDMA(&g_saiHandle, &sendXfer);

    // Waits for send to complete.
    while (!txFinished)
    {
    }

    // ...
}
```

Chapter 33
SMC: System Mode Controller Driver

33.1 Overview

The MCUXpresso SDK provides a peripheral driver for the System Mode Controller (SMC) module of MCUXpresso SDK devices. The SMC module sequences the system in and out of all low-power stop and run modes.

API functions are provided to configure the system for working in a dedicated power mode. For different power modes, SMC_SetPowerModexxx() function accepts different parameters. System power mode state transitions are not available between power modes. For details about available transitions, see the power mode transitions section in the SoC reference manual.

33.2 Typical use case

33.2.1 Enter wait or stop modes

SMC driver provides APIs to set MCU to different wait modes and stop modes. Pre and post functions are used for setting the modes. The pre functions and post functions are used as follows.

1. Disable/enable the interrupt through PRIMASK. This is an example use case. The application sets the wakeup interrupt and calls SMC function SMC_SetPowerModeStop to set the MCU to STOP mode, but the wakeup interrupt happens so quickly that the ISR completes before the function SMC_SetPowerModeStop. As a result, the MCU enters the STOP mode and never is woken up by the interrupt. In this use case, the application first disables the interrupt through PRIMASK, sets the wakeup interrupt, and enters the STOP mode. After wakeup, enable the interrupt through PRIMASK. The MCU can still be woken up by disabling the interrupt through PRIMASK. The pre and post functions handle the PRIMASK.
2. Disable/enable the flash speculation. When entering stop modes, the flash speculation might be interrupted. As a result, pre functions disable the flash speculation and post functions enable it.

```
SMC_PreEnterStopModes();

/* Enable the wakeup interrupt here. */

SMC_SetPowerModeStop(SMC, kSMC_PartialStop);

SMC_PostExitStopModes();
```

33.6 Function Documentation

33.6.1 static void SMC_SetPowerModeProtection (SMC_Type * *base,* uint8_t *allowedModes*) [inline], [static]

This function configures the power mode protection settings for supported power modes in the specified chip family. The available power modes are defined in the smc_power_mode_protection_t. This should be done at an early system level initialization stage. See the reference manual for details. This register can only write once after the power reset.

The allowed modes are passed as bit map. For example, to allow LLS and VLLS, use SMC_SetPowerModeProtection(kSMC_AllowPowerModeVlls | kSMC_AllowPowerModeVlps). To allow all modes, use SMC_SetPowerModeProtection(kSMC_AllowPowerModeAll).

Parameters

base	SMC peripheral base address.

33.6.2 static smc_power_state_t SMC_GetPowerModeState (SMC_Type * *base*) [inline], [static]

This function returns the current power mode status. After the application switches the power mode, it should always check the status to check whether it runs into the specified mode or not. The application should check this mode before switching to a different mode. The system requires that only certain modes can switch to other specific modes. See the reference manual for details and the smc_power_state_t for information about the power status.

35.2 UART Driver

35.2.1 Overview

The MCUXpresso SDK provides a peripheral driver for the Universal Asynchronous Receiver/Transmitter (UART) module of MCUXpresso SDK devices.

The UART driver includes functional APIs and transactional APIs.

Functional APIs are used for UART initialization/configuration/operation for optimization/customization purpose. Using the functional API requires the knowledge of the UART peripheral and how to organize functional APIs to meet the application requirements. All functional APIs use the peripheral base address as the first parameter. UART functional operation groups provide the functional API set.

Transactional APIs can be used to enable the peripheral quickly and in the application if the code size and performance of transactional APIs can satisfy the requirements. If the code size and performance are critical requirements, see the transactional API implementation and write custom code. All transactional APIs use the uart_handle_t as the second parameter. Initialize the handle by calling the UART_TransferCreateHandle() API.

Transactional APIs support asynchronous transfer, which means that the functions UART_TransferSendNonBlocking() and UART_TransferReceiveNonBlocking() set up an interrupt for data transfer. When the transfer completes, the upper layer is notified through a callback function with the kStatus_UART_TxIdle and kStatus_UART_RxIdle.

Transactional receive APIs support the ring buffer. Prepare the memory for the ring buffer and pass in the start address and size while calling the UART_TransferCreateHandle(). If passing NULL, the ring buffer feature is disabled. When the ring buffer is enabled, the received data is saved to the ring buffer in the background. The UART_TransferReceiveNonBlocking() function first gets data from the ring buffer. If the ring buffer does not have enough data, the function first returns the data in the ring buffer and then saves the received data to user memory. When all data is received, the upper layer is informed through a callback with the kStatus_UART_RxIdle.

If the receive ring buffer is full, the upper layer is informed through a callback with the kStatus_UART_RxRingBufferOverrun. In the callback function, the upper layer reads data out from the ring buffer. If not, existing data is overwritten by the new data.

The ring buffer size is specified when creating the handle. Note that one byte is reserved for the ring buffer maintenance. When creating handle using the following code.

```
UART_TransferCreateHandle(UART0, &handle, UART_UserCallback, NULL);
```

In this example, the buffer size is 32, but only 31 bytes are used for saving data.

35.2.2 Typical use case

35.2.2.1 UART Send/receive using a polling method

```
uint8_t ch;
```

```
UART_GetDefaultConfig(&user_config);
user_config.baudRate_Bps = 115200U;
user_config.enableTx = true;
user_config.enableRx = true;

UART_Init(UART1,&user_config,120000000U);

while(1)
{
    UART_ReadBlocking(UART1, &ch, 1);
    UART_WriteBlocking(UART1, &ch, 1);
}
```

35.2.2.2 UART Send/receive using an interrupt method

```

35.2.7 Function Documentation

35.2.7.1 status_t UART_Init (UART_Type * *base*, const uart_config_t * *config*, uint32_t *srcClock_Hz*)

This function configures the UART module with the user-defined settings. The user can configure the configuration structure and also get the default configuration by using the UART_GetDefaultConfig() function. The example below shows how to use this API to configure UART.

```
*  uart_config_t uartConfig;
*  uartConfig.baudRate_Bps = 115200U;
*  uartConfig.parityMode = kUART_ParityDisabled;
*  uartConfig.stopBitCount = kUART_OneStopBit;
*  uartConfig.txFifoWatermark = 0;
*  uartConfig.rxFifoWatermark = 1;
*  UART_Init(UART1, &uartConfig, 20000000U);
*
```

Parameters

base	UART peripheral base address.
config	Pointer to the user-defined configuration structure.
srcClock_Hz	UART clock source frequency in HZ.

Return values

kStatus_UART_Baudrate-NotSupport	Baudrate is not support in current clock source.
kStatus_Success	Status UART initialize succeed

35.2.7.2 void UART_Deinit (UART_Type * *base*)

This function waits for TX complete, disables TX and RX, and disables the UART clock.

Parameters

base	UART peripheral base address.

35.2.7.3 void UART_GetDefaultConfig (uart_config_t * *config*)

This function initializes the UART configuration structure to a default value. The default values are as follows. uartConfig->baudRate_Bps = 115200U; uartConfig->bitCountPerChar = kUART_8BitsPerChar; uartConfig->parityMode = kUART_ParityDisabled; uartConfig->stopBitCount = kUART_OneStopBit; uartConfig->txFifoWatermark = 0; uartConfig->rxFifoWatermark = 1; uartConfig->enableTx = false; uartConfig->enableRx = false;

Parameters

config	Pointer to configuration structure.

35.2.7.4 status_t UART_SetBaudRate (UART_Type * *base*, uint32_t *baudRate_Bps*, uint32_t *srcClock_Hz*)

This function configures the UART module baud rate. This function is used to update the UART module baud rate after the UART module is initialized by the UART_Init.

```
*  UART_SetBaudRate(UART1, 115200U, 20000000U);
*
```

Parameters

base	UART peripheral base address.
baudRate_Bps	UART baudrate to be set.
srcClock_Hz	UART clock source freqency in Hz.

Return values

kStatus_UART_Baudrate-NotSupport	Baudrate is not support in the current clock source.
kStatus_Success	Set baudrate succeeded.

35.2.7.5 uint32_t UART_GetStatusFlags (UART_Type * *base*)

This function gets all UART status flags. The flags are returned as the logical OR value of the enumerators _uart_flags. To check a specific status, compare the return value with enumerators in _uart_flags. For example, to check whether the TX is empty, do the following.

```
*     if (kUART_TxDataRegEmptyFlag & UART_GetStatusFlags(UART1))
*     {
*         ...
*     }
*
```

Parameters

base	UART peripheral base address.

Returns

UART status flags which are ORed by the enumerators in the _uart_flags.

35.2.7.6 status_t UART_ClearStatusFlags (UART_Type * *base*, uint32_t *mask*)

This function clears UART status flags with a provided mask. An automatically cleared flag can't be cleared by this function. These flags can only be cleared or set by hardware. kUART_TxDataRegEmpty-Flag, kUART_TransmissionCompleteFlag, kUART_RxDataRegFullFlag, kUART_RxActiveFlag, kUA-RT_NoiseErrorInRxDataRegFlag, kUART_ParityErrorInRxDataRegFlag, kUART_TxFifoEmptyFlag,k-UART_RxFifoEmptyFlag Note that this API should be called when the Tx/Rx is idle. Otherwise it has no effect.

Parameters

base	UART peripheral base address.
mask	The status flags to be cleared; it is logical OR value of _uart_flags.

Return values

kStatus_UART_Flag-CannotClearManually	The flag can't be cleared by this function but it is cleared automatically by hardware.
kStatus_Success	Status in the mask is cleared.

35.2.7.7 void UART_EnableInterrupts (UART_Type * *base*, uint32_t *mask*)

This function enables the UART interrupts according to the provided mask. The mask is a logical OR of enumeration members. See _uart_interrupt_enable. For example, to enable TX empty interrupt and RX full interrupt, do the following.

```
*     UART_EnableInterrupts(UART1,
      kUART_TxDataRegEmptyInterruptEnable |
      kUART_RxDataRegFullInterruptEnable);
*
```

Parameters

base	UART peripheral base address.
mask	The interrupts to enable. Logical OR of _uart_interrupt_enable.

35.2.7.8 void UART_DisableInterrupts (UART_Type * *base*, uint32_t *mask*)

This function disables the UART interrupts according to the provided mask. The mask is a logical OR of enumeration members. See _uart_interrupt_enable. For example, to disable TX empty interrupt and RX full interrupt do the following.

```
*     UART_DisableInterrupts(UART1,
      kUART_TxDataRegEmptyInterruptEnable |
      kUART_RxDataRegFullInterruptEnable);
*
```

Parameters

mask	The interrupts to disable. Logical OR of _uart_interrupt_enable.

35.2.7.9 uint32_t UART_GetEnabledInterrupts (UART_Type * *base*)

This function gets the enabled UART interrupts. The enabled interrupts are returned as the logical OR value of the enumerators _uart_interrupt_enable. To check a specific interrupts enable status, compare the return value with enumerators in _uart_interrupt_enable. For example, to check whether TX empty interrupt is enabled, do the following.

```
*     uint32_t enabledInterrupts = UART_GetEnabledInterrupts(UART1);
*
*     if (kUART_TxDataRegEmptyInterruptEnable & enabledInterrupts)
*     {
*         ...
*     }
*
```

Parameters

35.2.7.17 void UART_WriteBlocking (UART_Type * *base*, const uint8_t * *data*, size_t *length*)

This function polls the TX register, waits for the TX register to be empty or for the TX FIFO to have room and writes data to the TX buffer.

Note

This function does not check whether all data is sent out to the bus. Before disabling the TX, check kUART_TransmissionCompleteFlag to ensure that the TX is finished.

Parameters

base	UART peripheral base address.
data	Start address of the data to write.
length	Size of the data to write.

35.2.7.18 status_t UART_ReadBlocking (UART_Type * *base*, uint8_t * *data*, size_t *length*)

This function polls the RX register, waits for the RX register to be full or for RX FIFO to have data, and reads data from the TX register.

Parameters

base	UART peripheral base address.
data	Start address of the buffer to store the received data.
length	Size of the buffer.

35.2.7.19 void UART_TransferCreateHandle (UART_Type * *base*, uart_handle_t * *handle*, uart_transfer_callback_t *callback*, void * *userData*)

This function initializes the UART handle which can be used for other UART transactional APIs. Usually, for a specified UART instance, call this API once to get the initialized handle.

Parameters

base	UART peripheral base address.
handle	UART handle pointer.
callback	The callback function.
userData	The parameter of the callback function.

35.2.7.20 void UART_TransferStartRingBuffer (UART_Type * *base*, uart_handle_t * *handle*, uint8_t * *ringBuffer*, size_t *ringBufferSize*)

This function sets up the RX ring buffer to a specific UART handle.

When the RX ring buffer is used, data received are stored into the ring buffer even when the user doesn't call the UART_TransferReceiveNonBlocking() API. If data is already received in the ring buffer, the user can get the received data from the ring buffer directly.

Note

When using the RX ring buffer, one byte is reserved for internal use. In other words, if `ringBufferSize` is 32, only 31 bytes are used for saving data.

Parameters

base	UART peripheral base address.
handle	UART handle pointer.
ringBuffer	Start address of the ring buffer for background receiving. Pass NULL to disable the ring buffer.
ringBufferSize	Size of the ring buffer.

35.2.7.21 void UART_TransferStopRingBuffer (UART_Type * *base*, uart_handle_t * *handle*)

This function aborts the background transfer and uninstalls the ring buffer.

Parameters

base	UART peripheral base address.
handle	UART handle pointer.

35.2.7.22 status_t UART_TransferSendNonBlocking (UART_Type * *base*, uart_handle_t * *handle*, uart_transfer_t * *xfer*)

This function sends data using an interrupt method. This is a non-blocking function, which returns directly without waiting for all data to be written to the TX register. When all data is written to the TX register in the ISR, the UART driver calls the callback function and passes the kStatus_UART_TxIdle as status parameter.

Note

The kStatus_UART_TxIdle is passed to the upper layer when all data is written to the TX register. However, it does not ensure that all data is sent out. Before disabling the TX, check the kUART_TransmissionCompleteFlag to ensure that the TX is finished.

Parameters

base	UART peripheral base address.
handle	UART handle pointer.
xfer	UART transfer structure. See uart_transfer_t.

Return values

kStatus_Success	Successfully start the data transmission.
kStatus_UART_TxBusy	Previous transmission still not finished; data not all written to TX register yet.
kStatus_InvalidArgument	Invalid argument.

35.2.7.23 void UART_TransferAbortSend (UART_Type * *base*, uart_handle_t * *handle*)

Parameters

base	UART peripheral base address.
handle	UART handle pointer.

35.2.7.24 status_t UART_TransferGetSendCount (UART_Type * *base*, uart_handle_t * *handle*, uint32_t * *count*)

This function gets the number of bytes written to the UART TX register by using the interrupt method.

Parameters

base	UART peripheral base address.
handle	UART handle pointer.
count	Send bytes count.

Return values

kStatus_NoTransferInProgress	No send in progress.
kStatus_InvalidArgument	The parameter is invalid.
kStatus_Success	Get successfully through the parameter `count`;

35.2.7.25 status_t UART_TransferReceiveNonBlocking (UART_Type * *base*, uart_handle_t * *handle*, uart_transfer_t * *xfer*, size_t * *receivedBytes*)

This function receives data using an interrupt method. This is a non-blocking function, which returns without waiting for all data to be received. If the RX ring buffer is used and not empty, the data in the ring buffer is copied and the parameter `receivedBytes` shows how many bytes are copied from the ring buffer. After copying, if the data in the ring buffer is not enough to read, the receive request is saved by the UART driver. When the new data arrives, the receive request is serviced first. When all data is received, the UART driver notifies the upper layer through a callback function and passes the status parameter kStatus_UART_RxIdle. For example, the upper layer needs 10 bytes but there are only 5 bytes in the ring buffer. The 5 bytes are copied to the xfer->data and this function returns with the parameter `receivedBytes` set to 5. For the left 5 bytes, newly arrived data is saved from the xfer->data[5]. When 5 bytes are received, the UART driver notifies the upper layer. If the RX ring buffer is not enabled, this function enables the RX and RX interrupt to receive data to the xfer->data. When all data is received, the upper layer is notified.

Parameters

base	UART peripheral base address.
handle	UART handle pointer.
xfer	UART transfer structure, see uart_transfer_t.
receivedBytes	Bytes received from the ring buffer directly.

Return values

kStatus_Success	Successfully queue the transfer into transmit queue.
kStatus_UART_RxBusy	Previous receive request is not finished.
kStatus_InvalidArgument	Invalid argument.

35.2.7.26 void UART_TransferAbortReceive (UART_Type * *base*, uart_handle_t * *handle*)

This function aborts the interrupt-driven data receiving. The user can get the remainBytes to know how many bytes are not received yet.

Parameters

base	UART peripheral base address.
handle	UART handle pointer.

35.2.7.27 status_t UART_TransferGetReceiveCount (UART_Type * *base,* uart_handle_t * *handle,* uint32_t * *count*)

This function gets the number of bytes that have been received.

Parameters

base	UART peripheral base address.
handle	UART handle pointer.
count	Receive bytes count.

Return values

kStatus_NoTransferInProgress	No receive in progress.
kStatus_InvalidArgument	Parameter is invalid.
kStatus_Success	Get successfully through the parameter `count`;

35.2.7.28 void UART_TransferHandleIRQ (UART_Type * *base,* uart_handle_t * *handle*)

This function handles the UART transmit and receive IRQ request.

Parameters

base	UART peripheral base address.
handle	UART handle pointer.

Chapter 36
VREF: Voltage Reference Driver

36.1 Overview

The MCUXpresso SDK provides a peripheral driver for the Crossbar Voltage Reference (VREF) block of MCUXpresso SDK devices.

The Voltage Reference(VREF) supplies an accurate 1.2 V voltage output that can be trimmed in 0.5 mV steps. VREF can be used in applications to provide a reference voltage to external devices and to internal analog peripherals, such as the ADC, DAC, or CMP. The voltage reference has operating modes that provide different levels of supply rejection and power consumption.

To configure the VREF driver, configure vref_config_t structure in one of two ways.

1. Use the VREF_GetDefaultConfig() function.
2. Set the parameter in the vref_config_t structure.

To initialize the VREF driver, call the VREF_Init() function and pass a pointer to the vref_config_t structure.

To de-initialize the VREF driver, call the VREF_Deinit() function.

36.2 Typical use case and example

This example shows how to generate a reference voltage by using the VREF module.

```

Chapter 38
Clock Driver

38.1 Overview

The MCUXpresso SDK provides APIs for MCUXpresso SDK devices' clock operation.

38.2 Get frequency

A centralized function CLOCK_GetFreq gets different clock type frequencies by passing a clock name. For example, pass a kCLOCK_CoreSysClk to get the core clock and pass a kCLOCK_BusClk to get the bus clock. Additionally, there are separate functions to get the frequency. For example, use CLOCK-_GetCoreSysClkFreq to get the core clock frequency and CLOCK_GetBusClkFreq to get the bus clock frequency. Using these functions reduces the image size.

38.3 External clock frequency

The external clocks EXTAL0/EXTAL1/EXTAL32 are decided by the board level design. The Clock driver uses variables g_xtal0Freq/g_xtal1Freq/g_xtal32Freq to save clock frequencies. Likewise, the APIs CLOCK_SetXtal0Freq, CLOCK_SetXtal1Freq, and CLOCK_SetXtal32Freq are used to set these variables.

The upper layer must set these values correctly. For example, after OSC0(SYSOSC) is initialized using CLOCK_InitOsc0 or CLOCK_InitSysOsc, the upper layer should call the CLOCK_SetXtal0Freq. Otherwise, the clock frequency get functions may not receive valid values. This is useful for multicore platforms where only one core calls CLOCK_InitOsc0 to initialize OSC0 and other cores call CLOCK_SetXtal0-Freq.

38.5 Macro Definition Documentation

38.5.1 #define MCG_CONFIG_CHECK_PARAM 0U

Some MCG settings must be changed with conditions, for example:

1. MCGIRCLK settings, such as the source, divider, and the trim value should not change when MCGIRCLK is used as a system clock source.
2. MCG_C7[OSCSEL] should not be changed when the external reference clock is used as a system clock source. For example, in FBE/BLPE/PBE modes.
3. The users should only switch between the supported clock modes.

MCG functions check the parameter and MCG status before setting, if not allowed to change, the functions return error. The parameter checking increases code size, if code size is a critical requirement, change MCG_CONFIG_CHECK_PARAM to 0 to disable parameter checking.

38.5.2 #define FSL_SDK_DISABLE_DRIVER_CLOCK_CONTROL 0

When set to 0, peripheral drivers will enable clock in initialize function and disable clock in de-initialize function. When set to 1, peripheral driver will not control the clock, application could contol the clock out of the driver.

Note

All drivers share this feature switcher. If it is set to 1, application should handle clock enable and disable for all drivers.

38.8 Variable Documentation

38.8.1 uint32_t g_xtal0Freq

The XTAL0/EXTAL0 (OSC0) clock frequency in Hz. When the clock is set up, use the function CLOCK_SetXtal0Freq to set the value in the clock driver. For example, if XTAL0 is 8 MHz:

```
* CLOCK_InitOsc0(...); // Set up the OSC0
* CLOCK_SetXtal0Freq(80000000); // Set the XTAL0 value to the clock driver.
*
```

This is important for the multicore platforms where only one core needs to set up the OSC0 using the CLOCK_InitOsc0. All other cores need to call the CLOCK_SetXtal0Freq to get a valid clock frequency.

38.8.2 uint32_t g_xtal32Freq

The XTAL32/EXTAL32/RTC_CLKIN clock frequency in Hz. When the clock is set up, use the function CLOCK_SetXtal32Freq to set the value in the clock driver.

This is important for the multicore platforms where only one core needs to set up the clock. All other cores need to call the CLOCK_SetXtal32Freq to get a valid clock frequency.

38.9 Multipurpose Clock Generator (MCG)

The MCUXpresso SDK provides a peripheral driver for the module of MCUXpresso SDK devices.

38.9.1 Function description

MCG driver provides these functions:

- Functions to get the MCG clock frequency.
- Functions to configure the MCG clock, such as PLLCLK and MCGIRCLK.
- Functions for the MCG clock lock lost monitor.
- Functions for the OSC configuration.
- Functions for the MCG auto-trim machine.
- Functions for the MCG mode.

38.9.1.1 MCG frequency functions

MCG module provides clocks, such as MCGOUTCLK, MCGIRCLK, MCGFFCLK, MCGFLLCLK and MCGPLLCLK. The MCG driver provides functions to get the frequency of these clocks, such as CLOCK_GetOutClkFreq(), CLOCK_GetInternalRefClkFreq(), CLOCK_GetFixedFreqClkFreq(), CLOCK_GetFllFreq(), CLOCK_GetPll0Freq(), CLOCK_GetPll1Freq(), and CLOCK_GetExtPllFreq(). These functions get the clock frequency based on the current MCG registers.

38.9.1.2 MCG clock configuration

The MCG driver provides functions to configure the internal reference clock (MCGIRCLK), the external reference clock, and MCGPLLCLK.

The function CLOCK_SetInternalRefClkConfig() configures the MCGIRCLK, including the source and the driver. Do not change MCGIRCLK when the MCG mode is BLPI/FBI/PBI because the MCGIRCLK is used as a system clock in these modes and changing settings makes the system clock unstable.

The function CLOCK_SetExternalRefClkConfig() configures the external reference clock source (MCG_C7[OSCSEL]). Do not call this function when the MCG mode is BLPE/FBE/PBE/FEE/PEE because the external reference clock is used as a clock source in these modes. Changing the external reference clock source requires at least a 50 microseconds wait. The function CLOCK_SetExternalRefClkConfig() implements a for loop delay internally. The for loop delay assumes that the system clock is 96 MHz, which ensures at least 50 micro seconds delay. However, when the system clock is slow, the delay time may significantly increase. This for loop count can be optimized for better performance for specific cases.

The MCGPLLCLK is disabled in FBE/FEE/FBI/FEI modes by default. Applications can enable the MCGPLLCLK in these modes using the functions CLOCK_EnablePll0() and CLOCK_EnablePll1(). To enable the MCGPLLCLK, the PLL reference clock divider(PRDIV) and the PLL VCO divider(VDIV) must be set to a proper value. The function CLOCK_CalcPllDiv() helps to get the PRDIV/VDIV.

38.9.1.3 MCG clock lock monitor functions

The MCG module monitors the OSC and the PLL clock lock status. The MCG driver provides the functions to set the clock monitor mode, check the clock lost status, and clear the clock lost status.

38.9.1.4 OSC configuration

The MCG is needed together with the OSC module to enable the OSC clock. The function CLOCK_InitOsc0() CLOCK_InitOsc1 uses the MCG and OSC to initialize the OSC. The OSC should be configured based on the board design.

38.9.1.5 MCG auto-trim machine

The MCG provides an auto-trim machine to trim the MCG internal reference clock based on the external reference clock (BUS clock). During clock trimming, the MCG must not work in FEI/FBI/BLPI/PBI/PEI modes. The function CLOCK_TrimInternalRefClk() is used for the auto clock trimming.

38.9.1.6 MCG mode functions

The function CLOCK_GetMcgMode returns the current MCG mode. The MCG can only switch between the neighbouring modes. If the target mode is not current mode's neighbouring mode, the application must choose the proper switch path. For example, to switch to PEE mode from FEI mode, use FEI -> FBE -> PBE -> PEE.

For the MCG modes, the MCG driver provides three kinds of functions:

The first type of functions involve functions CLOCK_SetXxxMode, such as CLOCK_SetFeiMode(). These functions only set the MCG mode from neighbouring modes. If switching to the target mode directly from current mode is not possible, the functions return an error.

The second type of functions are the functions CLOCK_BootToXxxMode, such as CLOCK_BootToFeiMode(). These functions set the MCG to specific modes from reset mode. Because the source mode and target mode are specific, these functions choose the best switch path. The functions are also useful to set up the system clock during boot up.

The third type of functions is the CLOCK_SetMcgConfig(). This function chooses the right path to switch to the target mode. It is easy to use, but introduces a large code size.

Whenever the FLL settings change, there should be a 1 millisecond delay to ensure that the FLL is stable. The function CLOCK_SetMcgConfig() implements a for loop delay internally to ensure that the FLL is stable. The for loop delay assumes that the system clock is 96 MHz, which ensures at least 1 millisecond delay. However, when the system clock is slow, the delay time may increase significantly. The for loop count can be optimized for better performance according to a specific use case.

38.9.2 Typical use case

The function CLOCK_SetMcgConfig is used to switch between any modes. However, this heavy-light function introduces a large code size. This section shows how to use the mode function to implement a quick and light-weight switch between typical specific modes. Note that the step to enable the external clock is not included in the following steps. Enable the corresponding clock before using it as a clock source.

38.9.3 Code Configuration Option

38.9.3.1 MCG_USER_CONFIG_FLL_STABLE_DELAY_EN

When switching to use FLL with function CLOCK_SetFeiMode() and CLOCK_SetFeeMode(), there is an internal function CLOCK_FllStableDelay(). It is used to delay a few ms so that to wait the FLL to be stable enough. By default, it is implemented in driver code like:

```
#ifndef MCG_USER_CONFIG_FLL_STABLE_DELAY_EN
void CLOCK_FllStableDelay(void)
{
    /*
```

```
       Should wait at least 1ms. Because in these modes, the core clock is 100MHz
       at most, so this function could obtain the 1ms delay.
     */
    volatile uint32_t i = 30000U;
    while (i--)
    {
        __NOP();
    }
}
#endif /* MCG_USER_CONFIG_FLL_STABLE_DELAY_EN */
```

Once user is willing to create his own delay funcion, just assert the macro MCG_USER_CONFIG_FLL-_STABLE_DELAY_EN, and then define function CLOCK_FllStableDelay in the application code.

Chapter 40
Memory-Mapped Cryptographic Acceleration Unit (MMCAU)

40.1 Overview

The mmCAU software library uses the mmCAU co-processor that is connected to the ARM Cortex-M4/-M0+ Private Peripheral Bus (PPB). In this chapter, CAU refers to both CAU and mmCAU unless explicitly noted.

40.2 Purpose

The following chapter describes how to use the mmCAU software library in any application to integrate a cryptographic algorithm or hashing function supported by the software library. NXP products supported by the software library are MCU/MPUs. Check the specific Freescale product for CAU availability.

40.3 Library Features

The library is as compact and generic as possible to simplify the integration with existing cryptographic software. The library has a standard header file with ANSI C prototypes for all functions: "cau_api.h". This software library is thread safe only if CAU registers are saved on a context switch. The mmCAU software library is also compatible to ARM C compiler conventions (EABI). All pointers passed to mmCAU API functions (input and output data blocks, keys, key schedules, and so on) are aligned to 0-modulo-4 addresses.

For applications that don't need to deal with the aligned addresses, a simple wrapper layer is provided. The wrapper layer consists of the "fsl_mmcau.h" header file and "fsl_mmcau.c" source code file. The only function of the wrapper layer is that it supports unaligned addresses

. The CAU library supports the following encryption/decryption algorithms and hashing functions:

- AES128
- AES192
- AES256
- DES
- MD5
- SHA1
- SHA256

Note: 3DES crypto algorithms are supported by calling the corresponding DES crypto function three times. Hardware support for SHA256 is only present in the CAU version 2. See the appropriate MCU/MPU reference manual for details about availability. Additionally, the cau_sha256_initialize_output() function checks the hardware revision and returns a (-1) value if the CAU lacks SHA256 support.

/* SPI_Init(). */

/* Register the SDSPI driver callback. */

/* Initializes card. */
if (kStatus_Success != SDSPI_Init(card))
{
    SDSPI_Deinit(card)
    return;
}

/* Read/Write card */
memset(g_testWriteBuffer, 0x17U, sizeof(g_testWriteBuffer));

while (true)
{
    memset(g_testReadBuffer, 0U, sizeof(g_testReadBuffer));

    SDSPI_WriteBlocks(card, g_testWriteBuffer, TEST_START_BLOCK, TEST_BLOCK_COUNT);

    SDSPI_ReadBlocks(card, g_testReadBuffer, TEST_START_BLOCK, TEST_BLOCK_COUNT);

    if (memcmp(g_testReadBuffer, g_testReadBuffer, sizeof(g_testWriteBuffer)))
    {
        break;
    }
}

Chapter 43
Debug Console

43.1 Overview

This chapter describes the programming interface of the debug console driver.

The debug console enables debug log messages to be output via the specified peripheral with frequency of the peripheral source clock and base address at the specified baud rate. Additionally, it provides input and output functions to scan and print formatted data.

43.2 Function groups

43.2.1 Initialization

To initialize the debug console, call the DbgConsole_Init() function with these parameters. This function automatically enables the module and the clock.

```
/*
 * @brief Initializes the the peripheral used to debug messages.
 *
 * @param baseAddr      Indicates which address of the peripheral is used to send debug messages.
 * @param baudRate      The desired baud rate in bits per second.
 * @param device        Low level device type for the debug console, can be one of:
 *                      @arg DEBUG_CONSOLE_DEVICE_TYPE_UART,
 *                      @arg DEBUG_CONSOLE_DEVICE_TYPE_LPUART,
 *                      @arg DEBUG_CONSOLE_DEVICE_TYPE_LPSCI,
 *                      @arg DEBUG_CONSOLE_DEVICE_TYPE_USBCDC.
 * @param clkSrcFreq    Frequency of peripheral source clock.
 *
 * @return              Whether initialization was successful or not.
 */
status_t DbgConsole_Init(uint32_t baseAddr, uint32_t baudRate, uint8_t device, uint32_t clkSrcFreq)
```

Selects the supported debug console hardware device type, such as

```
DEBUG_CONSOLE_DEVICE_TYPE_NONE
DEBUG_CONSOLE_DEVICE_TYPE_LPSCI
DEBUG_CONSOLE_DEVICE_TYPE_UART
DEBUG_CONSOLE_DEVICE_TYPE_LPUART
DEBUG_CONSOLE_DEVICE_TYPE_USBCDC
```

After the initialization is successful, stdout and stdin are connected to the selected peripheral. The debug console state is stored in the debug_console_state_t structure, such as shown here.

```
typedef struct DebugConsoleState
{
    uint8_t                    type;
    void*                      base;
    debug_console_ops_t        ops;
} debug_console_state_t;
```

This example shows how to call the DbgConsole_Init() given the user configuration structure.

```
uint32_t uartClkSrcFreq = CLOCK_GetFreq(BOARD_DEBUG_UART_CLKSRC);

DbgConsole_Init(BOARD_DEBUG_UART_BASEADDR, BOARD_DEBUG_UART_BAUDRATE, DEBUG_CONSOLE_DEVICE_TYPE_UART,
      uartClkSrcFreq);
```

43.2.2 Advanced Feature

The debug console provides input and output functions to scan and print formatted data.

- Support a format specifier for PRINTF following this prototype " %[flags][width][.precision][length]specifier", which is explained below

flags	Description
-	Left-justified within the given field width. Right-justified is the default.
+	Forces to precede the result with a plus or minus sign (+ or -) even for positive numbers. By default, only negative numbers are preceded with a - sign.
(space)	If no sign is written, a blank space is inserted before the value.
#	Used with o, x, or X specifiers the value is preceded with 0, 0x, or 0X respectively for values other than zero. Used with e, E and f, it forces the written output to contain a decimal point even if no digits would follow. By default, if no digits follow, no decimal point is written. Used with g or G the result is the same as with e or E but trailing zeros are not removed.
0	Left-pads the number with zeroes (0) instead of spaces, where padding is specified (see width sub-specifier).

Width	Description
(number)	A minimum number of characters to be printed. If the value to be printed is shorter than this number, the result is padded with blank spaces. The value is not truncated even if the result is larger.
*	The width is not specified in the format string, but as an additional integer value argument preceding the argument that has to be formatted.

.precision	Description
.number	For integer specifiers (d, i, o, u, x, X) precision specifies the minimum number of digits to be written. If the value to be written is shorter than this number, the result is padded with leading zeros. The value is not truncated even if the result is longer. A precision of 0 means that no character is written for the value 0. For e, E, and f specifiers this is the number of digits to be printed after the decimal point. For g and G specifiers This is the maximum number of significant digits to be printed. For s this is the maximum number of characters to be printed. By default, all characters are printed until the ending null character is encountered. For c type it has no effect. When no precision is specified, the default is 1. If the period is specified without an explicit value for precision, 0 is assumed.
.*	The precision is not specified in the format string, but as an additional integer value argument preceding the argument that has to be formatted.

length	Description
Do not support	

specifier	Description
d or i	Signed decimal integer
f	Decimal floating point
F	Decimal floating point capital letters
x	Unsigned hexadecimal integer
X	Unsigned hexadecimal integer capital letters
o	Signed octal
b	Binary value
p	Pointer address
u	Unsigned decimal integer
c	Character
s	String of characters
n	Nothing printed

- Support a format specifier for SCANF following this prototype " %[∗][width][length]specifier", which is explained below

∗	Description
An optional starting asterisk indicates that the data is to be read from the stream but ignored. In other words, it is not stored in the corresponding argument.	

width	Description
This specifies the maximum number of characters to be read in the current reading operation.	

length	Description
hh	The argument is interpreted as a signed character or unsigned character (only applies to integer specifiers: i, d, o, u, x, and X).
h	The argument is interpreted as a short integer or unsigned short integer (only applies to integer specifiers: i, d, o, u, x, and X).
l	The argument is interpreted as a long integer or unsigned long integer for integer specifiers (i, d, o, u, x, and X) and as a wide character or wide character string for specifiers c and s.
ll	The argument is interpreted as a long long integer or unsigned long long integer for integer specifiers (i, d, o, u, x, and X) and as a wide character or wide character string for specifiers c and s.
L	The argument is interpreted as a long double (only applies to floating point specifiers: e, E, f, g, and G).
j or z or t	Not supported

specifier	Qualifying Input	Type of argument
c	Single character: Reads the next character. If a width different from 1 is specified, the function reads width characters and stores them in the successive locations of the array passed as argument. No null character is appended at the end.	char ∗

specifier	Qualifying Input	Type of argument
i	Integer: : Number optionally preceded with a + or - sign	int *
d	Decimal integer: Number optionally preceded with a + or - sign	int *
a, A, e, E, f, F, g, G	Floating point: Decimal number containing a decimal point, optionally preceded by a + or - sign and optionally followed by the e or E character and a decimal number. Two examples of valid entries are -732.103 and 7.12e4	float *
o	Octal Integer:	int *
s	String of characters. This reads subsequent characters until a white space is found (white space characters are considered to be blank, newline, and tab).	char *
u	Unsigned decimal integer.	unsigned int *

The debug console has its own printf/scanf/putchar/getchar functions which are defined in the header file.

```
int DbgConsole_Printf(const char *fmt_s, ...);
int DbgConsole_Putchar(int ch);
int DbgConsole_Scanf(const char *fmt_ptr, ...);
int DbgConsole_Getchar(void);
```

This utility supports selecting toolchain's printf/scanf or the MCUXpresso SDK printf/scanf.

```
#if SDK_DEBUGCONSOLE    /* Select printf, scanf, putchar, getchar of SDK version. */
#define PRINTF                DbgConsole_Printf
#define SCANF                 DbgConsole_Scanf
#define PUTCHAR               DbgConsole_Putchar
#define GETCHAR               DbgConsole_Getchar
#else                   /* Select printf, scanf, putchar, getchar of toolchain. */
#define PRINTF                printf
#define SCANF                 scanf
#define PUTCHAR               putchar
#define GETCHAR               getchar
#endif /* SDK_DEBUGCONSOLE */
```

43.3 Typical use case

Some examples use the PUTCHAR & GETCHAR function

```
ch = GETCHAR();
PUTCHAR(ch);
```

Typical use case

Some examples use the PRINTF function

Statement prints the string format.

```
PRINTF("%s %s\r\n", "Hello", "world!");
```

Statement prints the hexadecimal format/

```
PRINTF("0x%02X hexadecimal number equivalents 255", 255);
```

Statement prints the decimal floating point and unsigned decimal.

```
PRINTF("Execution timer: %s\n\rTime: %u ticks %2.5f milliseconds\n\rDONE\n\r", "1 day", 86400, 86.4);
```

Some examples use the SCANF function

```
PRINTF("Enter a decimal number: ");
SCANF("%d", &i);
PRINTF("\r\nYou have entered %d.\r\n", i, i);
PRINTF("Enter a hexadecimal number: ");
SCANF("%x", &i);
PRINTF("\r\nYou have entered 0x%X (%d).\r\n", i, i);
```

Print out failure messages using KSDK __assert_func:

```
void __assert_func(const char *file, int line, const char *func, const char *failedExpr)
{
    PRINTF("ASSERT ERROR \" %s \": file \"%s\" Line \"%d\" function name \"%s\" \n", failedExpr, file ,
      line, func);
    for (;;)
    {}
}
```

Note:

To use 'printf' and 'scanf' for GNUC Base, add file **'fsl_sbrk.c'** in path: **..\{package}\devices\{subset}\utilities\fsl_sbrk.c** to your project.

Modules

- Semihosting

43.4 Semihosting

Semihosting is a mechanism for ARM targets to communicate input/output requests from application code to a host computer running a debugger. This mechanism can be used, for example, to enable functions in the C library, such as printf() and scanf(), to use the screen and keyboard of the host rather than having a screen and keyboard on the target system.

43.4.1 Guide Semihosting for IAR

NOTE: After the setting both "printf" and "scanf" are available for debugging.

Step 1: Setting up the environment

1. To set debugger options, choose Project>Options. In the Debugger category, click the Setup tab.
2. Select Run to main and click OK. This ensures that the debug session starts by running the main function.
3. The project is now ready to be built.

Step 2: Building the project

1. Compile and link the project by choosing Project>Make or F7.
2. Alternatively, click the Make button on the tool bar. The Make command compiles and links those files that have been modified.

Step 3: Starting semihosting

1. Choose "Semihosting_IAR" project -> "Options" -> "Debugger" -> "J-Link/J-Trace".
2. Choose tab "J-Link/J-Trace" -> "Connection" tab -> "SWD".
3. Start the project by choosing Project>Download and Debug.
4. Choose View>Terminal I/O to display the output from the I/O operations.

43.4.2 Guide Semihosting for Keil µVision

NOTE: Keil supports Semihosting only for Cortex-M3/Cortex-M4 cores.

Step 1: Prepare code

Remove function fputc and fgetc is used to support KEIL in "fsl_debug_console.c" and add the following code to project.

```
#pragma import(__use_no_semihosting_swi)

volatile int ITM_RxBuffer = ITM_RXBUFFER_EMPTY;       /* used for Debug Input */
```

```
struct __FILE
{
    int handle;
};
FILE __stdout;
FILE __stdin;

int fputc(int ch, FILE *f)
{
    return (ITM_SendChar(ch));
}

int fgetc(FILE *f)
{ /* blocking */
    while (ITM_CheckChar() != 1)
        ;
    return (ITM_ReceiveChar());
}

int ferror(FILE *f)
{
    /* Your implementation of ferror */
    return EOF;
}

void _ttywrch(int ch)
{
    ITM_SendChar(ch);
}

void _sys_exit(int return_code)
{
label:
    goto label; /* endless loop */
}
```

Step 2: Setting up the environment

1. In menu bar, choose Project>Options for target or using Alt+F7 or click.
2. Select "Target" tab and not select "Use MicroLIB".
3. Select “Debug” tab, select “J-Link/J-Trace Cortex” and click “Setting button”.
4. Select “Debug” tab and choose Port:SW, then select "Trace" tab, choose "Enable" and click OK.

Step 3: Building the project

1. Compile and link the project by choosing Project>Build Target or using F7.

Step 4: Building the project

1. Choose “Debug” on menu bar or Ctrl F5.
2. In menu bar, choose "Serial Window" and click to "Debug (printf) Viewer".
3. Run line by line to see result in Console Window.

43.4.3 Guide Semihosting for KDS

NOTE: After the setting use "printf" for debugging.

Step 1: Setting up the environment

1. In menu bar, choose Project>Properties>C/C++ Build>Settings>Tool Settings.
2. Select “Libraries” on “Cross ARM C Linker” and delete “nosys”.
3. Select “Miscellaneous” on "Cross ARM C Linker”, add “-specs=rdimon.specs” to “Other link flages” and tick “Use newlib-nano”, and click OK.

Step 2: Building the project

1. In menu bar, choose Project>Build Project.

Step 3: Starting semihosting

1. In Debug configurations, choose "Startup" tab, tick “Enable semihosting and Telnet”. Press “Apply” and “Debug”.
2. After clicking Debug, the Window is displayed same as below. Run line by line to see the result in the Console Window.

43.4.4 Guide Semihosting for ATL

NOTE: J-Link has to be used to enable semihosting.

Step 1: Prepare code

Add the following code to the project.

```
int _write(int file, char *ptr, int len)
{
  /* Implement your write code here. This is used by puts and printf. */
  int i=0;
  for(i=0 ; i<len ; i++)
    ITM_SendChar((*ptr++));
  return len;
}
```

Step 2: Setting up the environment

1. In menu bar, choose Debug Configurations. In tab "Embedded C/C++ Aplication" choose "-Semihosting_ATL_xxx debug J-Link".
2. In tab "Debugger" set up as follows.
   - JTAG mode must be selected

- SWV tracing must be enabled
- Enter the Core Clock frequency, which is hardware board-specific.
- Enter the desired SWO Clock frequency. The latter depends on the JTAG Probe and must be a multiple of the Core Clock value.

3. Click "Apply" and "Debug".

Step 3: Starting semihosting

1. In the Views menu, expand the submenu SWV and open the docking view “SWV Console". 2. Open the SWV settings panel by clicking the "Configure Serial Wire Viewer" button in the SWV Console view toolbar. 3. Configure the data ports to be traced by enabling the ITM channel 0 check-box in the ITM stimulus ports group: Choose "EXETRC: Trace Exceptions" and In tab "ITM Stimulus Ports" choose "Enable Port" 0. Then click "OK".
2. It is recommended not to enable other SWV trace functionalities at the same time because this may over use the SWO pin causing packet loss due to a limited bandwidth (certain other SWV tracing capabilities can send a lot of data at very high-speed). Save the SWV configuration by clicking the OK button. The configuration is saved with other debug configurations and remains effective until changed.
3. Press the red Start/Stop Trace button to send the SWV configuration to the target board to enable SWV trace recoding. The board does not send any SWV packages until it is properly configured. The SWV Configuration must be present, if the configuration registers on the target board are reset. Also, tracing does not start until the target starts to execute.
4. Start the target execution again by pressing the green Resume Debug button.
5. The SWV console now shows the printf() output.

43.4.5 Guide Semihosting for ARMGCC

Step 1: Setting up the environment

2. Run "build_debug.bat" to build project

Step 3: Starting semihosting

(a) Download the image and set as follows.

```
cd D:\mcu-sdk-2.0-origin\boards\twrk64f120m\driver_examples\semihosting\armgcc\debug
d:
C:\PROGRA~2\GNUTOO~1\4BD65~1.920\bin\arm-none-eabi-gdb.exe
target remote localhost:2331
monitor reset
monitor semihosting enable
monitor semihosting thumbSWI 0xAB

load semihosting_ARMGCC.elf
monitor reg pc = (0x00000004)
monitor reg sp = (0x00000000)
continue
```

(b) After the setting, press "enter". The PuTTY window now shows the printf() output.

Chapter 44
Notification Framework

44.1 Overview

This section describes the programming interface of the Notifier driver.

44.2 Notifier Overview

The Notifier provides a configuration dynamic change service. Based on this service, applications can switch between pre-defined configurations. The Notifier enables drivers and applications to register callback functions to this framework. Each time that the configuration is changed, drivers and applications receive a notification and change their settings. To simplify, the Notifier only supports the static callback registration. This means that, for applications, all callback functions are collected into a static table and passed to the Notifier.

These are the steps for the configuration transition.

1. Before configuration transition, the Notifier sends a "BEFORE" message to the callback table. When this message is received, IP drivers should check whether any current processes can be stopped and stop them. If the processes cannot be stopped, the callback function returns an error.
   The Notifier supports two types of transition policies, a graceful policy and a forceful policy. When the graceful policy is used, if some callbacks return an error while sending a "BEFORE" message, the configuration transition stops and the Notifier sends a "RECOVER" message to all drivers that have stopped. Then, these drivers can recover the previous status and continue to work. When the forceful policy is used, drivers are stopped forcefully.
2. After the "BEFORE" message is processed successfully, the system switches to the new configuration.
3. After the configuration changes, the Notifier sends an "AFTER" message to the callback table to notify drivers that the configuration transition is finished.

This example shows how to use the Notifier in the Power Manager application.

```
#include "fsl_notifier.h"

// Definition of the Power Manager callback.
status_t callback0(notifier_notification_block_t *notify, void *data)
{

    status_t ret = kStatus_Success;

    ...
    ...
    ...

    return ret;
}
// Definition of the Power Manager user function.
status_t APP_PowerModeSwitch(notifier_user_config_t *targetConfig, void *userData)
{
```

```
    ...
    ...
    ...
}
...
...
...
...
...
// Main function.
int main(void)
{
    // Define a notifier handle.
    notifier_handle_t powerModeHandle;

    // Callback configuration.
    user_callback_data_t callbackData0;

    notifier_callback_config_t callbackCfg0 = {callback0,
                kNOTIFIER_CallbackBeforeAfter,
                (void *)&callbackData0};

    notifier_callback_config_t callbacks[] = {callbackCfg0};

    // Power mode configurations.
    power_user_config_t vlprConfig;
    power_user_config_t stopConfig;

    notifier_user_config_t *powerConfigs[] = {&vlprConfig, &stopConfig};

    // Definition of a transition to and out the power modes.
    vlprConfig.mode = kAPP_PowerModeVlpr;
    vlprConfig.enableLowPowerWakeUpOnInterrupt = false;

    stopConfig = vlprConfig;
    stopConfig.mode = kAPP_PowerModeStop;

    // Create Notifier handle.
    NOTIFIER_CreateHandle(&powerModeHandle, powerConfigs, 2U, callbacks, 1U,
      APP_PowerModeSwitch, NULL);
    ...
    ...
    // Power mode switch.
    NOTIFIER_switchConfig(&powerModeHandle, targetConfigIndex,
      kNOTIFIER_PolicyAgreement);
}
```

44.4 Typedef Documentation

44.4.1 typedef void notifier_user_config_t

Reference of the user defined configuration is stored in an array; the notifier switches between these configurations based on this array.

44.4.2 typedef status_t(* notifier_user_function_t)(notifier_user_config_t *targetConfig, void *userData)

Before and after this function execution, different notification is sent to registered callbacks. If this function returns any error code, NOTIFIER_SwitchConfig() exits.

Parameters

targetConfig	target Configuration.
userData	Refers to other specific data passed to user function.

Returns

An error code or kStatus_Success.

44.4.3 typedef status_t(∗ notifier_callback_t)(notifier_notification_block_t ∗notify, void ∗data)

Declaration of a callback. It is common for registered callbacks. Reference to function of this type is part of the notifier_callback_config_t callback configuration structure. Depending on callback type, function of this prototype is called (see NOTIFIER_SwitchConfig()) before configuration switch, after it or in both use cases to notify about the switch progress (see notifier_callback_type_t). When called, the type of the notification is passed as a parameter along with the reference to the target configuration structure (see notifier_notification_block_t) and any data passed during the callback registration. When notified before the configuration switch, depending on the configuration switch policy (see notifier_policy_t), the callback may deny the execution of the user function by returning an error code different than kStatus_Success (see NOTIFIER_SwitchConfig()).

Parameters

notify	Notification block.
data	Callback data. Refers to the data passed during callback registration. Intended to pass any driver or application data such as internal state information.

Returns

An error code or kStatus_Success.

44.5 Enumeration Type Documentation

44.5.1 enum _notifier_status

Used as return value of Notifier functions.

Enumerator

kStatus_NOTIFIER_ErrorNotificationBefore An error occurs during send "BEFORE" notification.

kStatus_NOTIFIER_ErrorNotificationAfter An error occurs during send "AFTER" notification.

44.5.2 enum notifier_policy_t

Defines whether the user function execution is forced or not. For kNOTIFIER_PolicyForcible, the user function is executed regardless of the callback results, while kNOTIFIER_PolicyAgreement policy is used to exit NOTIFIER_SwitchConfig() when any of the callbacks returns error code. See also NOTIFIER_SwitchConfig() description.

Enumerator

kNOTIFIER_PolicyAgreement NOTIFIER_SwitchConfig() method is exited when any of the callbacks returns error code.
kNOTIFIER_PolicyForcible The user function is executed regardless of the results.

44.5.3 enum notifier_notification_type_t

Used to notify registered callbacks

Enumerator

kNOTIFIER_NotifyRecover Notify IP to recover to previous work state.
kNOTIFIER_NotifyBefore Notify IP that configuration setting is going to change.
kNOTIFIER_NotifyAfter Notify IP that configuration setting has been changed.

44.5.4 enum notifier_callback_type_t

Used in the callback configuration structure (notifier_callback_config_t) to specify when the registered callback is called during configuration switch initiated by the NOTIFIER_SwitchConfig(). Callback can be invoked in following situations.

- Before the configuration switch (Callback return value can affect NOTIFIER_SwitchConfig() execution. See the NOTIFIER_SwitchConfig() and notifier_policy_t documentation).
- After an unsuccessful attempt to switch configuration
- After a successful configuration switch

Enumerator

kNOTIFIER_CallbackBefore Callback handles BEFORE notification.
kNOTIFIER_CallbackAfter Callback handles AFTER notification.
kNOTIFIER_CallbackBeforeAfter Callback handles BEFORE and AFTER notification.

44.6 Function Documentation

44.6.1 status_t NOTIFIER_CreateHandle (notifier_handle_t * *notifierHandle,* notifier_user_config_t ** *configs,* uint8_t *configsNumber,* notifier_callback_config_t * *callbacks,* uint8_t *callbacksNumber,* notifier_user_function_t *userFunction,* void * *userData*)

Parameters

notifierHandle	A pointer to the notifier handle.
configs	A pointer to an array with references to all configurations which is handled by the Notifier.
configsNumber	Number of configurations. Size of the configuration array.
callbacks	A pointer to an array of callback configurations. If there are no callbacks to register during Notifier initialization, use NULL value.
callbacks-Number	Number of registered callbacks. Size of the callbacks array.
userFunction	User function.
userData	User data passed to user function.

Returns

An error Code or kStatus_Success.

44.6.2 status_t NOTIFIER_SwitchConfig (notifier_handle_t * *notifierHandle,* uint8_t *configIndex,* notifier_policy_t *policy*)

This function sets the system to the target configuration. Before transition, the Notifier sends notifications to all callbacks registered to the callback table. Callbacks are invoked in the following order: All registered callbacks are notified ordered by index in the callbacks array. The same order is used for before and after switch notifications. The notifications before the configuration switch can be used to obtain confirmation about the change from registered callbacks. If any registered callback denies the configuration change, further execution of this function depends on the notifier policy: the configuration change is either forced (kNOTIFIER_PolicyForcible) or exited (kNOTIFIER_PolicyAgreement). When configuration change is forced, the result of the before switch notifications are ignored. If an agreement is required, if any callback returns an error code, further notifications before switch notifications are cancelled and all already notified callbacks are re-invoked. The index of the callback which returned error code during pre-switch notifications is stored (any error codes during callbacks re-invocation are ignored) and NOTIFIER_GetErrorCallback() can be used to get it. Regardless of the policies, if any callback returns an error code, an error code indicating in which phase the error occurred is returned when NOTIFIER_SwitchConfig() exits.

Parameters

notifierHandle	pointer to notifier handle
configIndex	Index of the target configuration.
policy	Transaction policy, kNOTIFIER_PolicyAgreement or kNOTIFIER_PolicyForcible.

Returns

An error code or kStatus_Success.

44.6.3 uint8_t NOTIFIER_GetErrorCallbackIndex (notifier_handle_t * *notifierHandle*)

This function returns an index of the last callback that failed during the configuration switch while the last NOTIFIER_SwitchConfig() was called. If the last NOTIFIER_SwitchConfig() call ended successfully value equal to callbacks number is returned. The returned value represents an index in the array of static call-backs.

Parameters

notifierHandle	Pointer to the notifier handle

Returns

Callback Index of the last failed callback or value equal to callbacks count.

```
SHELL_Init(&user_context, SHELL_SendDataCallback, SHELL_ReceiveDataCallback, "SHELL>> ");
